MODERN PLASTICS ENCYCLOPEDIA ISSUE

SEPTEMBER 1957

Volume 35, Number 1A

Modern Plastics Executive and Editorial Offices: 575 Madison Ave., New York 22, N. Y.

Modern Plastics published monthly by Breskin Publications, Inc., at Emmett St., Bristol, Conn. Modern Plastics Encyclopedia Issue published as second issue in September by Plastics Catalogue Corp., at Emmett St., Bristol, Conn. Subscription rates (including Modern Plastics Encyclopedia Issue), payable in U. S. currency: In United States, its possessions, and Canada, 1 year $7, 2 years $12, 3 years $17; all other countries, 1 year $20, 2 years $35, 3 years $50. Single copies 75¢ each (Show issue, $1.00, Encyclopedia Issue $3.00) in the U. S., its possessions, and Canada; all other countries $2.00 (Show issue $2.50, Encyclopedia Issue $6.00). Modern Plastics Encyclopedia Issue copyright 1957 by Plastics Catalogue Corp. All rights reserved. Nothing that appears in the Modern Plastics Encyclopedia Issue may be reprinted wholly or in part without first securing special permission. Printed in U.S.A. by Hildreth Press, Inc., Bristol, Conn.
*Reg. U.S. Pat. Off.

FOREWORD

As a reflection of the expansion which the plastics industries experienced during the past year, the scope of information offered in the 1957 Modern Plastics Encyclopedia Issue has been considerably broadened to take in the latest in materials, processing, and application developments. Every effort has been made as well to present this wealth of information in such a manner as to facilitate the job of selecting specific data quickly and easily.

The popular Plastics Properties Chart, for example, which seems to grow bigger every year, has not only been revised to include new materials, but has been completely redesigned in the form of a bar chart to increase its value as a working tool for the industry. By supplementing numerical values, these bars serve as a visual guide to the user seeking materials with specific properties.

With an eye to the new developments that have taken place within the past year and the new technical language that has come into being, both the Primer of Plastics and the Plastics Glossary have been expanded.

The Resins and Molding Compounds section has also come in for several changes this year. Every article has been reviewed and up-dated by authoritative experts in each field, with special emphasis being placed in those areas where technological developments have been breaking at a fast and furious pace. The articles on styrene copolymers, nylons, and ethylene polymers, among others, stand out in this respect.

Again reflecting the interests of the plastics industries, an entirely new section on Foamed Plastics has been incorporated in this year's Encyclopedia.

In the Engineering and Methods section, readers will find a series of tables that offer a concise and handy guide to the molding characteristics of the individual materials

covered in each of the accompanying articles. Another innovation in this section is the inclusion of a set of articles surveying the basic theories of injection molding, compression molding, and extrusion. And in the Fabricating and Finishing section, as well as in the Machinery and Equipment section, recent developments have been digested in outline form to provide a quick review of the year's activities.

Other special interests which occupied the plastics industries during the past year, from new techniques for preforming fibrous glass to instrumentation, are individually covered in appropriate articles. The Directory Section, as always, carries an authoritative listing of manufacturers, molders, suppliers, etc., as well as a list of Trade Designations.

In using the 1957 Encyclopedia Issue, readers are advised to refer first to the key Index, beginning on page 30. As a further guide, an Index of Advertisers whose products and/or services are related to the subject matter of individual sections can be found at the beginning of each section.

Readers should also bear in mind the availability of Modern Plastics Encyclopedia's editorial and advertising staffs as a source for additional information on any subject covered in the editorial or advertising pages of this issue. Inquiries addressed to the Readers Service Department will be given prompt attention. To aid in their processing, it is recommended that readers include with their inquiries the page number of the editorial page or the advertising page on which they are seeking additional information.

ACKNOWLEDG

No volume of the scope of Modern Plastics Encyclopedia could be prepared without the complete cooperation of the industry which it serves. As always, such cooperation was cheerfully extended for the 1957 Edition. The Editors wish, therefore, to express their sincere thanks to the authors whose names appear on various articles, as well as to the companies and individuals listed below for supplying information, illustrations, and helpful suggestions.

Achhammer, B. G.

Acryvin Corp. of America—Carl L. Shapiro

Adhesive Products Corp.—J. E. Conrad

Adhesive Products, Inc., The—W. F. Harrison

Allied Resinous Products, Inc.—N. K. Anderson

Ambassador Plastics and Mfg. Co.—L. Corwin

Amercoat Corp.—L. R. Smith

American Agile Corp.—C. F. Freedman

American-British Chemical Supplies, Inc.—H. K. Vanderhoef

American Cyanamid Co.—H. J. West, Ted Wennergren, Norman Prince

American Hard Rubber Co.—G. H. Reed

American Insulator Corp.—M. F. Lloyd

American Latex Products Corp.—George Morris

American Marietta Co.—D. V. Redfern, W. E. Van Vactor

American Mineral Spirits Co.—R. M. Pegram

American Products Mfg. Co.—H. A. Levey

American Pyroxylin Corp.—M. Goldberg

American Reinforced Sales—H. B. Sait

American Viscose Corp.—Charles R. Shaffer

Anchor Plastics Co., Inc.—Robert Marx

Angier Products, Inc.—Harold J. Thoma

Archer-Daniels-Midland Co.—R. S. Mathews, C. S. Stryker

Argus Chemical Corp. Norman L. Perry

Armour and Co.—(Adhesive Div.) L. B. Lane, (Chemical Div.) Harry J. Delfs, Jr.

Armstrong Products Co.—F. E. Harrison

Arnold, Hoffman & Co., Inc.—Kenneth W. Bean

PRIMER OF PLASTICS

The accepted definition of plastics is: "a large and varied group of materials which consist of, or contain as an essential ingredient, a substance of high molecular weight which, while solid in the finished state, at some stage in its manufacture is soft enough to be formed into various shapes, most usually through the application, either singly or together, of heat and pressure."

Most plastics, with the exception of the cellulosics, which are chemically modified natural high polymers made from cotton, are produced by the synthesis from such natural resources as water, air, coal, salt, natural gas, etc. From these are derived the various chemicals and gases which are combined to produce the plastics materials. As an example, the raw materials for making polystyrene, one of the most important of the plastics, are coal and petroleum or natural gas. By a process of distillation, benzene is extracted from the coal; from the petroleum or natural gas is taken the gas ethylene. These two materials are then linked to form ethyl benzene which is dehydrogenated to styrene. With the aid of catalysts, heat, and pressure, thousands of styrene molecules polymerize, or link together, to form long chain-like molecules that clump into small granules of crude polystyrene. These grains are hot-worked and cut into small pellets called molding powder, the most common form in which plastics are supplied.

Because of the many source materials which the chemist has at his command, and because so many different combinations are possible, the family of plastics today encompasses a large—and still growing—number of members, all of which differ in properties and characteristics. If, for example, the ethylene gas used in producing polystyrene were combined with chlorine (from salt) and then polymerized, the result would be polyvinyl chloride—a very different plastic.

Major Sub-Divisions

Many combinations and many different materials are thus possible. Therefore, for purposes of simplification, most plastics can be classified under one of the 14 recognized basic family groups. These groups, in turn, can be *generally* further classified under one of two major sub-divisions—thermosetting or thermoplastics. A few plastics are in-between—they can be formulated either to be thermosetting or to be thermoplastic.

The thermosets, as the term implies, set or harden (cure) under heat into a permanent shape. An irreversible chemical reaction called cross-linking occurs; this reaction links the resin chains so that the molded piece is essentially one giant, three-dimensional molecule. Subsequent heating, though it may soften the structure somewhat, cannot restore the flowability that typifies the uncured resin. In this classification are such basic family groups as the aminos (melamine and urea), most polyesters, alkyds, epoxies, and phenolics.

The thermoplastics, on the other hand, soften when heat is applied and harden upon cooling. By alternate heating and cooling, they can be reshaped again and again (just as a cake of ice melts in the sun and the resulting water can be solidified into a different shape by freezing). Thermoplastics include styrene polymers and copolymers, acrylics, cellulosics, polyethylenes, vinyls, nylons, and fluorocarbons.

Alloying of plastics yields new types of materials with intermediate physical and chemical properties. Similarly, plastics can be combined with other materials to create a new end-product having the advantages of both. Important examples are the blends of styrene-acrylonitrile or styrene-butadiene resins and rubbers which exhibit the hardness and high heat resistance of the resin and the toughness and low brittle point of the rubber. By copolymerizing (polymerizing together) two monomers, products similar to the alloyed polymers can be obtained, often at less expense.

Types of Plastics

A brief summary of the various types of plastics materials available, their properties and applications, may help to give the layman some idea of the versatility which plastics have to offer and the extent to which they have already penetrated our daily lives.

AMINOS (Urea and melamine): Urea formaldehyde resin is derived from the reaction of urea (carbamide) with formaldehyde or its polymers. Consumers are probably most familiar with the cosmetic containers, buttons, and electric mixer housings molded of urea to take advantage of the material's solvent-, oil-, and grease-resistance, surface hardness, mar-resistance, color potential, and good electric insulating qualities. Less familiar is the use of urea in liquid form in adhesives for plywood and lumber core gluing and laminating, in textile and paper treating resins, and in surface coatings that provide marproof finishes. Melamine formaldehyde resin is classed as a synthetic resin derived from the reaction of melamine (prepared from dicyandiamide) with formaldehyde. In addi-

tion to its well-known use in the molding of high-grade dinnerware and tableware, melamine is also used for critical military parts, industrial and decorative household appliances, handles, buttons, and other products. As a laminating resin, it goes into the manufacture of shockproof laminates and decorative laminates for household and office use. Melamine resins are also used in the formulation of boilproof, durable adhesives, in leather tanning, in the treatment of textiles, and in the production of wet-strength paper.

POLYESTERS: By definition, a polyester is a resin composed of polymeric esters in which the recurring ester groups are an integral part of the main polymer chain. Unsaturated polyesters contain double bonds which permit cross-linking and hence conversion of the resin to a substantially infusible and insoluble product. While some polyesters are used for casting applications (e.g., aircraft glazing, potting of electrical components, buttons, etc.), the bulk of the resin is used in the so-called "reinforced plastics" products. Because the polyesters are easily handled liquids that can be cured easily and quickly to a solid material without any liquid or gases being evolved, they can be reinforced with fibrous glass, asbestos, synthetic fibers, etc., and molded (either with or without pressure and with or without heat) into complex shapes characterized by high-impact strength, light weight, good dimensional stability, and good electrical properties. Products being molded today of reinforced polyester resins include: building panels, electrical equipment parts, boats, aircraft components, tote boxes, chairs, laundry tubs, automobile bodies and other components, luggage, awnings, etc.

ALKYDS: An alkyd is a type of synthetic resin described as an oil-modified polyester resin. As surface coatings, the alkyds provide a tough, versatile, uniform, and economical finish. Alkyd moldings exhibit excellent dimensional stability and electrical characteristics and are being used as tuner boards, tube bases, automotive ignition parts, etc.

PHENOLICS: Made by reacting phenol with aldehydes, phenolics are strong, rigid, dimensionally stable materials, resistant to heat and a wide variety of solvents, and, most important, a nonconductor of electricity. Phenolic moldings find application as light plugs, electric switch boxes, washing machine agitators, vacuum cleaner parts, and camera cases among others. In liquid form, phenolic is used in the manufacture of industrial and decorative laminates, as a protective coating, and as an adhesive. The plywood industry, which uses almost 10% of all the phenolic resin manufactured, is the largest customer for phenolic resin adhesives. Phenolic resins also find volume use in thermal insulation and in the manufacture of brake bands, which further account for a large share of total usage.

POLYSTYRENE: Polystyrene is a water-white thermoplastic produced by the polymerization of styrene (vinyl benzene). The general-purpose materials offer such outstanding advantages as: light weight, availability in a wide range of colors as well as in crystal-clear, freedom from taste and odor, nontoxicity, and exceptionally good electrical properties over the whole range of frequencies in practical use. General-purpose materials are used in the molding of a wide range of products, from disposable packages and refrigerator parts to toys, housewares, wall tile, and signs and displays. More recently, a whole new group of styrene materials with specialized properties (e.g., heat-resistant styrenes, light-stabilized styrenes, glass-reinforced styrenes, etc.) have been made available. One of the most important of the new groups are styrenes that have been toughened by copolymerization with butadiene and/or acrylonitrile. These rugged copolymers are being molded into pipe fittings, wheels, helmets, valve parts, refrigerator parts, toys, etc., or extruded into pipe that is being widely used by the petroleum industry. Sheeting based on this material is being formed into automobile headliners and kick plates, typewriter cases, refrigerator door liners, tote boxes, trays, and a wide variety of functional and/or decorative housings.

ACRYLICS: Basically, acrylics constitute a family that comprises monomers and polymers of acrylic, substituted acrylics, and methacrylic acids, their salts, esters, and other derivatives, such as nitriles and amides. In the form of sheets and molding powders, the properties exhibited by the solid acrylic polymers, such as crystal clarity, high impact strength, ease of formability, and resistance to sunlight, weather, and most chemicals, have led to their widespread use in a range of military and civilian applications that includes: airplane canopies; radar plotting boards; signs and displays; light diffusers; industrial window glazing; shower enclosures; automotive parts (taillight and stoplight lenses, medallions, instrument panels, etc.); and control knobs, dials, and handles. Acrylic resins also play an important role in the formulation of paints, clear greaseproof paper coatings, adhesives, and coatings for leather finishing applications.

CELLULOSICS: The family of cellulosics comprise such a wide variety of materials, e.g., cellulose acetate, cellulose acetate butyrate, cellulose nitrate, cellulose propionate, ethyl cellulose, etc., that to explain and define each would take up considerably more space than is allotted here. To mention just two, however, cellulose acetate plastics are notable for their outstanding toughness and high-impact strength, and are used for toys, beads, cutlery handles, knobs, electrical parts, ladies shoe heels, and housings. In sheet form, cellulose acetate is widely used as a packaging material and for electric insulation and tape. The

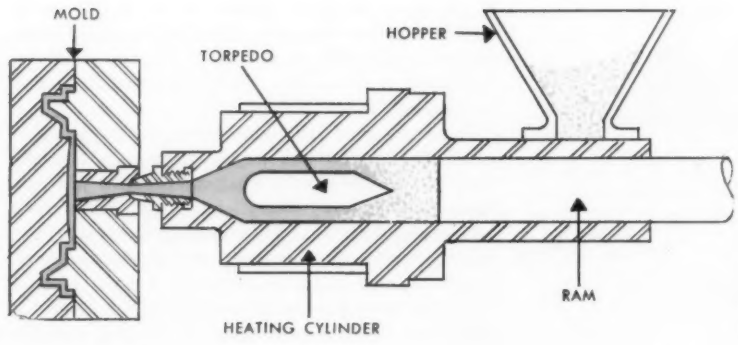
primary physical properties of cellulose acetate butyrate are a hornlike toughness, high-impact strength, uniform texture, dimensional stability under normally varying conditions of temperature and humidity, and low moisture absorption. One of the large-volume applications for butyrate can be found in extruded pipe.

POLYETHYLENE: Basically, polyethylene is synthesized by the polymerization of ethylene at elevated temperatures and pressures in the presence of suitable catalysts. Conventional low-density polyethylene requires very high synthesis pressures (15,000 to 30,000 p.s.i.) and uses free radical catalysts, such as peroxides. The newer stiff, high-density polyethylenes are made at lower synthesis pressures, using coordination catalysts. There is still confusion as to just where the new polyethylenes (with their greater strength, stiffness, and heat resistance) will fit into the application picture. The conventional polyethylenes, with their flexibility, durability, light weight, resistance to moisture, excellent chemical resistance, and retention of strength at freezing temperatures, already have found a number of important markets. These include: molded housewares, film and sheeting for the building industry, the agricultural field, and the packaging industry; electrical insulation in the form of outer jackets for power cables, telephone lines, appliance wire, etc.; extruded pipe for farm, mine, and home uses; coatings for paper, aluminum foil, and other sheet materials; squeeze bottles and tubes; and extruded monofilaments.

VINYL: This family of plastics takes in a wide group of resins, e.g., polyvinyl acetate, polyvinyl acetals, polyvinyl alcohol, etc., the most important of which is polyvinyl chloride. Polyvinyl chloride is described as a thermoplastic material composed of polymers of vinyl chloride. It is a colorless solid with outstanding resistance to water, alcohols, and concentrated acids and alkalies. One of the initial uses of vinyl chloride resins—electrical insulation—is still an extremely large market today. In the form of film and sheet, vinyl chloride resins have also found a virtually inexhaustible market that already includes shower curtains, inflatables, vapor barriers, silo covers, and upholstery. Floor covering is also a big outlet as are extruded products. Most of these products are made of plasticized (softened) vinyl.

NYLON: Nylons are polymeric resins formed by the condensation of dibasic organic acids with diamines into linear chains containing amide groups. The various grades of nylons available (nylon 6, nylon 6/6, nylon 6/10, etc.) have several outstanding features in common: they are stiff, strong, tough, light, abrasion-resistant, have a low coefficient of friction, and are chemically and thermally resistant. Nylon is finding application in the form of molded gears and bushings, housings, cams, and aerosol bottles. The use of nylon as a jacket for wire and cables is already well-established, but newer extrusion applications, including the possibility of a tough nylon film for packaging uses are attracting attention.

OTHER RESINS: The FLUOROCARBONS, EPOXIES, and SILICONES are coming more and more into the picture. The fluorocarbons with their good thermal and chemical resistance, nonadhesiveness, low dissipation factor, and low dielectric constant, are finding use in such applications as corrosion-resistant pipe or as an insulating material. Epoxies are strong, light in weight, shrinkproof, and resistant to water and heat. They are used as surface coatings, in adhesives, in laminates, in castings (particularly in the tooling field and for potting of delicate electronic components). Reinforced with fibrous glass, they are finding important use for such structural and electrical applications as radomes, terminal boards, printed electronic circuits, aircraft skins, etc. The silicones contribute excellent weather, heat, and wear resistance to an end-product. Silicones exist in a wide range of physical forms, from simple fluids through greases and flexible rubbers to hard, durable resins of complex structures. Among their applications are silicone rubbers; molding compounds for use in gaskets, circuit breakers, etc.; laminating resins for instances where high-temperature operation is required; release agents; lubricants; adhesives; and coatings.



Processing Methods

Before they are processed, most basic plastics resins can be combined—compounded—with any one of a large range of modifying chemicals or reinforcing materials in varying proportions to achieve a given end result. Such additions can take the form of plasticizers (which soften the plastic and make it more flexible), stabilizers (which prevent degradation in the plastic when it is exposed to heat or light), fillers (which add bulk and reduce over-all costs), colorants (which add integral color to the processed plastic end-product), and reinforcing fibers (which improve impact strength, electrical properties, etc., of finished product). Solvents are used in plastics compositions to give the degree of temporary fluidity necessary to such operations as dipping, brushing, spraying, etc., and catalysts are often added to speed up the cure of a compound.

After compounding, the resultant plastics are supplied in convenient liquid, granular, and powdered forms to processors.

From granular or powdered form, they are softened and shaped by molding or extrusion. They can also be transformed into flexible film or sheeting by extrusion or calendering. Sheets in turn may be resoftened and shaped into contoured products.

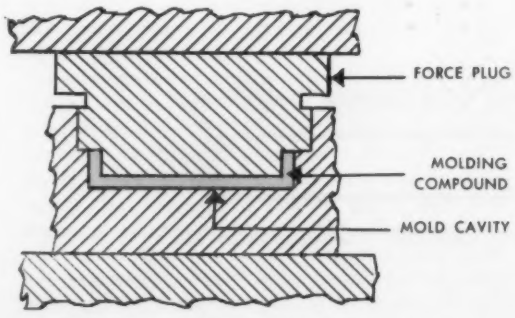
In liquid form, the plastics are used as spray-on, dip-on, and brush-on coatings, or incorporated into lacquers, paints, and adhesives. Plastic-based

INJECTION MOLDING: Pellets of plastic resin (in color) feeding from hopper are melted in the heating cylinder and forced forward by the ram into the mold

bonding agents are among the best. Liquid plastics are also cast into sheets.

By mechanical mixing or by the addition of chemical blowing agents, liquid plastics resins can also be foamed into a cellular product for insulation, cushioning, floatation applications, etc.

Of these methods of processing, molding consumes the largest volume of material. Molding procedures are all based on the fact that, when the plastic is heated, it will melt to a viscous liquid that can be forced into a mold of desired shape, where it solidifies.



Injection Molding

Different molding processes have been developed to handle the specialized properties of the various plastics. Injection molding, for example, is the most commonly used method for producing thermoplastic end-products.

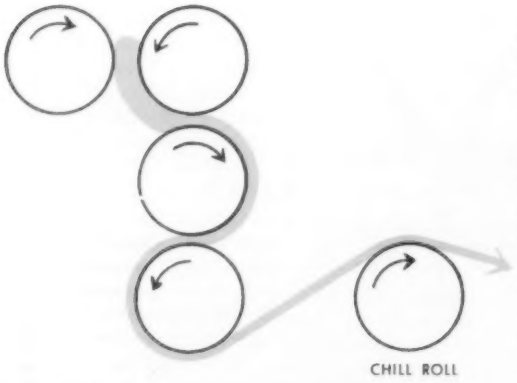
In injection molding, pellets are first fed from the hopper into the rear end of the heating cylinder where heating starts. With successive strokes of the injection ram the material is compacted and forced forward through the thin annular space between a heated "torpedo" in the center of the cylinder and the cylinder walls. There the material is melted. Soon it reaches the cylinder nozzle and is injected into the cold mold.

The fluid plastic completely fills the mold cavity, which is shaped to the contours of the finished product. When the plastic has cooled and solidified, the mold is opened and the finished piece, an exact image of the mold cavity, is ejected.

To speed up molding cycles and facilitate production, preplasticators are available. A preplasticator is simply an auxiliary heating cylinder which melts the granules and transfers the melt to the injection cylinder where it is further heated and held ready for injection.

COMPRESSION MOLDING: Plastic is pressed into cavity

Compression Molding



For molding the thermosetting plastics, the method most generally used is compression molding. The basic procedure is to place the molding compound (generally preheated) in the open mold cavity, close the mold, and then apply heat and pressure (through a downward-moving force plug) to the material until it softens and is forced to fill the mold cavity. In the closed mold, the material undergoes a chemical reaction that cross-links the polymer chains and thus hardens into a permanent shape. The mold is then opened and the solid piece is removed.

Transfer molding is a variation on compression molding in which the heat and pressure are applied to the molding material outside the mold. The fluid material is then forced through a series of channels (runners) from the external chamber to the mold cavity where final cure takes place.

Extrusion

For the production of continuous film, sheeting, rods, tubes, and other profile shapes (as distinguished from molded shapes), extrusion, another of the major processing divisions, is the method commonly employed.

In extrusion, the powdered or granular material is fed through a hopper at the rear of the unit into a heated barrel where it is plasticated by heat and working. The hot melt is then forced forward by a continuously revolving screw through the heating chamber and out through a shaping orifice or die, much as meat is forced through a grinder. As the plastic shape, which can be anything from a thick

CALENDERING: Plastic is squeezed flat between rollers

rod or large pipe to a thin sheet or thread-like monofilament, depending upon the size and shape of the die, is forced out, it is usually conveyed through a water bath that sets the shape.

Plastics can also be extruded as coatings around continuous lengths of wire or cable.

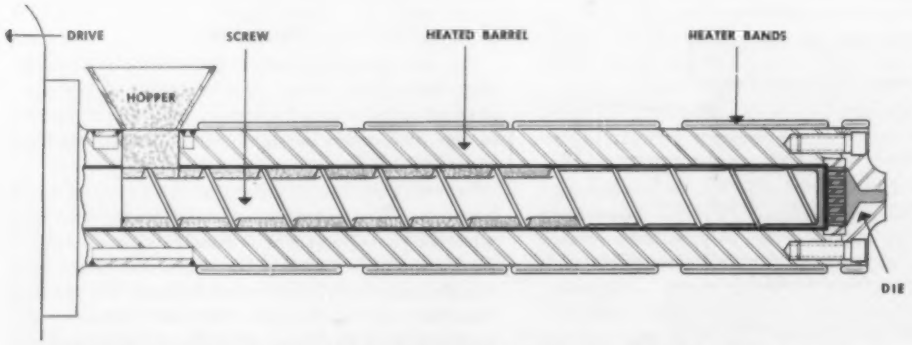
While these three techniques—injection, compression, and extrusion—account for the production of the major share of plastics products, other variations in molding techniques are possible. In blow molding, for example, which is used in the production of plastics bottles, thermoplastics sheets or charges from an extrusion machine are placed in closed molds and are forced into final form by being blown into these molds with air or steam pressure. Pulp molding and jet molding are other techniques used for specialized applications.

Casting

Although these molding methods differ in many respects from each other, they all have one thing in common—the use of heat and external pressure. Where no pressure is used, the process is known as casting. In casting, the plastic (either thermoplastic or thermosetting) is supplied in liquid form or in granular or powdered form that can be liquefied by heating or by the addition of solvents, catalysts, etc. The fluid plastic is poured into a mold and is cured into a solid at room temperature or by further heating.

Many variations in casting techniques are also possible. One method used for making flexible toys, overshoes, etc., is slush molding, in which a thermoplastic resin slurry (or "slush") is poured into a warm mold. The heat homogenizes the slurry into a viscous layer of the desired wall thickness, and the excess slurry is then poured out. The resin left in the mold is fully fused by additional heat, then chilled; in its final flexible form, it is simply stripped out of the mold.

Casting is also involved in one of the other two techniques which, in addition to extrusion, are available for the production of plastics film and sheet (film generally refers to sheeting 0.010 in. and thinner). When casting film or sheet, the liquid plastics material is cast on a moving belt or by precipitation in a chemical bath.



Calendering

The third major technique for turning out film and sheet is known as calendering. In calendering, the plastics compound, usually in the form of a warm doughy mass, is passed between a series of heated rollers in which it is thoroughly worked. It emerges from the rolls squeezed into flat film or sheet, the uniform thickness of which is detering, the plastics compound, usually in the form of (gaging rolls), and is cooled on a chill roll.

Calendering can also be used to apply a plastics covering to such backing materials as paper, fabric, etc. The film and backing material are simply squeezed together in the heated rollers.

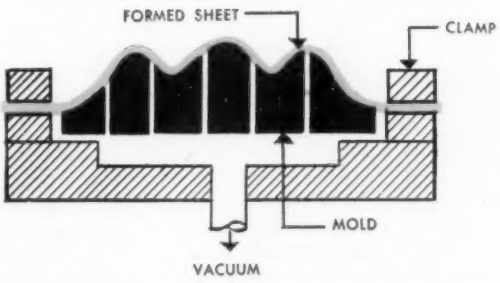
Fabricating and Finishing

After plastics film, sheet, or extruded or molded shapes have been produced, additional operations are sometimes necessary before the final plastics product is ready for market. These operations generally fall under the classification of either

EXTRUSION: Softened plastic is forced by revolving screw through heated barrel and out of die

"fabricating" or "finishing," or both. Fabricating rigid plastics involves changing the size or the shape of the molded or extruded piece, adding holes or openings, etc., by such conventional metal- or wood-working techniques as drilling, tapping, turning, milling, etc. Fabricating flexible plastics film or sheeting involves cutting the material to size (film and sheeting are generally produced in continuous rolls or are available in stock sheet sizes) and turning it into an end product by sewing, heat-sealing (bonding or welding the material to itself or to other materials), etc.

The term "finishing" is generally applied to operations, e.g., tumbling, sanding, etc., for improving the surface appearance of molded plastics pieces by removing flash (excess material at the parting line) and other extraneous matter, as well as to the various decorating techniques used. When working with rigid plastics, surface decoration can take the form of stamping, printing, spraying, or vacuum metalizing (in which a metal coating is deposited on the plastic). Film, sheet, or coated materials can be metalized, printed with colorful patterns, or embossed or flocked to simulate virtually any type of surface texture.



Sheet Forming

One of the most important fabricating operations —and one that has virtually grown into an entire industry of its own—is that of heat-forming film or sheeting. The basic principle is this: the heat-softened film or sheet is forced against a cold mold, permanently taking on the contours of the mold. A wide range of forming methods have been developed, differing primarily in the manner in which the sheet is heated and in the type of external pressure used to force it against the mold.

Laminates and Reinforced Plastics

Many plastics, usually liquids at room temperature, are used as binders and surfacing materials in conjunction with reinforcing materials such as fibrous glass, synthetic fibers, paper, wood, etc. Uses for plastics in this area divide into three basic categories: surface coating materials (paints, varnishes, lacquers, and coatings for fabrics, paper, etc.); bonding materials (resins to bond sand in the manufacture of foundry cores and abrasives in the manufacture of grinding wheels, etc.); and laminating materials.

For purposes of simplification, the latter classification can be further broken down into two main product groups—high-pressure laminates and low-pressure laminates. As the names imply, the difference is in the amount of pressure used in processing, but the gap is closing and higher and higher pressures are being used to produce better and better "low-pressure" laminates. The latter are commonly referred to as "reinforced plastics," although the designation could be applied to any resin reinforced with any fibers.

SHEET FORMING: Vacuum pulls heated sheet onto mold

In making a high-pressure laminate, sheets of the reinforcing material are impregnated with the liquid plastic resin and subjected to heat and high pressures while they cure into a single piece of uniform thickness. High-pressure laminates are sub-divided into decorative laminates, such as are used for counters and tabletops, and industrial laminates, which are machined into such industrial components as gears and bearings.

In molding reinforced plastics, woven cloths or nonwoven mats of the reinforcing material (glass, synthetic fibers, asbestos, etc.) are also impregnated with resin, but the laminate can be cured with little or no pressure. Molding a reinforced plastic product can be as simple as placing pre-cut pieces of reinforcing materials in an open mold, impregnating them with liquid plastic, and curing at room temperature and atmospheric pressure. However, the use of closed "matched metal" molds in heavy compression presses is becoming standard practice for the mass-production of reinforced plastics parts. It is faster and gives denser products with more closely controlled dimensions.

Combinations of Materials

To obtain the individual advantages of different plastics materials in a single product, techniques have been developed for combining materials. Laminating, for example, using heat and pressure, can be used for uniting different types of plastics film and sheeting.

"Sandwiches" are another combination material for which many uses are predicted. A sandwich construction is a multi-layered laminate formed by bonding (generally with synthetic resin adhesives) two thin, strong facings (plastics, metal, wood, etc.) to a thick, lightweight core (foamed plastics, balsa wood, honeycombs, etc.) that separates and stabilizes the thin facings, thus giving them much greater stiffness.

This *Primer of Plastics* touches only on the highlights of the industry. For complete discussions of specific phases, consult the Subject Index, p. 30; for definitions of words and phrases, see the Plastics Glossary that starts on the next page.

PLASTICS GLOSSARY

A

A-STAGE—An early stage in the reaction of a thermosetting resin in which the material is still soluble in certain liquids and fusible. See also *B-* and *C-Stage*.

ABSOLUTE VISCOSITY—Of a fluid, the tangential force on unit area of either of two parallel planes at unit distance apart when the space between the planes is filled with the fluid in question and one of the planes moves with unit differential velocity in its own plane.

The C.G.S. unit for absolute (or dynamic) viscosity is the poise (dyne-sec./sq. cm.). The centipoise (0.01 poise) is often used.

ACCELERATOR—A substance that hastens a reaction, particularly one which speeds up the vulcanization of rubber. Also known as *Promoter*.

ACRYLIC ESTER—An ester of acrylic acid, or of a structural derivative of acrylic acid, e.g., methyl methacrylate.

ACRYLIC RESIN—A synthetic resin prepared from acrylic acid or from a derivative of acrylic acid.

ACRYLONITRILE—A monomer with the structure (CH_2:CHCN). It is most useful in copolymers. Its copolymer with butadiene is nitrile rubber, and several copolymers with styrene exist that are tougher than polystyrene. It is also used as a synthetic fiber and as a chemical intermediate.

ADAPTOR PLATE—In injection molding, the plate holding mold which fits press or platen.

ADDITION POLYMERIZATION—See *Polymerization*.

ADHESION—The state in which two surfaces are held together by interfacial forces which may consist of valence forces or interlocking action or both.

ADHESIVE—A substance capable of holding materials together by surface attachment. Adhesive is the general term and includes, among others, the synthetic resin adhesives as well as the vegetable and animal base adhesives, such as cements, glues, mucilages, and pastes. These terms are sometimes used loosely and interchangeably.

ADSORPTION—The adhesion of the molecules of gases, dissolved substances, or liquids in more or less concentrated form to the surfaces of solids or liquids with which they are in contact.

AGING—The change in properties of a material with time under stated conditions.

ALIPHATIC HYDROCARBONS—Hydrocarbons having an open chain structure. Familiar examples include gasoline and propane.

ALKYD—Type of synthetic resin prepared from interaction of acids and alcohols. See *Polyester*.

ALLOY—Composite material made up by blending polymers or copolymers with other polymers or elastomers under selected conditions, e.g., styrene-acrylonitrile copolymer resins blended with butadiene-acrylonitrile rubbers.

ALLYL RESIN—A synthetic resin formed by the polymerization of chemical compounds containing the group $CH_2{=}CH-CH_2-$.

ALPHA-CELLULOSE—A very pure cellulose prepared by special chemical treatment.

AMINO—Indicates the presence of an $-NH_2$ or $-NH$ group.

ANGLE PRESS—Type of press used for compression and transfer molding having both a vertical and a horizontal ram, the latter being used for clamping. Developed for molding pieces having inside threads and undercuts.

ANNEALING—A process of holding a material at a temperature near, but below, its melting point, the objective being to permit stress relaxation without distortion of shape. It is often used on molded articles to relieve stresses set up by flow into the mold.

ANTIOXIDANT—Substance which prevents or slows down oxidation of material exposed to air.

ARC RESISTANCE—Time required for a given electrical current to render the surface of a material conductive because of carbonization by the arc flame.

AROMATIC HYDROCARBONS—Hydrocarbons derived from or characterized by the presence of unsaturated ring structures.

ASPHALT—A dark-colored viscous to solid hydrocarbon complex including: *a*) the easily fusible bitumens often associated with a mineral matrix, not having a waxy luster or unctuous feel; *b*) fusible residuums obtained from the distillation, etc., of bitumens.

ATOMIC WEIGHT—Relative weight of an atom of any element as compared with that of one atom of oxygen taken as 16.

AUTOCLAVE—1) Closed strong vessel for conducting chemical reactions under high pressure; 2) in low-pressure laminating, a round or cylindrical container in which heat and fluid pressure can be applied to resin-impregnated paper or fabric positioned in layers over a mold.

AUTOMATIC MOLD—Specially designed mold adaptable to a completely automatic molding machine.

B

B-STAGE—An intermediate stage in the reaction of a thermosetting resin in which the material softens when heated and swells in contact with certain liquids but does not entirely fuse or dissolve. Resins in thermosetting molding compounds are usually in this stage. See also *A-Stage* and *C-Stage*.

BACKING PLATE—In injection molding, a plate used as a support for the cavity blocks, guide pins, bushings, etc.

BAG MOLDING—A method of applying pressure during bonding or molding, in which a flexible cover, usually in connection with a rigid die or mold, exerts pressure on the material being molded, through the application of air pressure or drawing of a vacuum.

BENZENE RING—Graphic representation of the benzene nucleus, a ring of six carbon atoms believed

to exist in the aromatic compounds. In benzene, 6 hydrogen atoms are joined to the ring.

BETA GAGE—Electronic device that continuously measures the thickness of sheet products without contacting the material being gaged.

BLANKING—The cutting of flat sheet stock to shape by striking it sharply with a punch while it is supported on a mating die. Punch presses are used. Also called *Die Cutting*.

BLEED—To give up color when in contact with water or a solvent; undesired movement of certain materials in a plastic (e.g., plasticizers in vinyl) to the surface of the finished article or into an adjacent material. Also called *Migration*.

BLISTER—A raised area on the surface of a molding caused by the pressure of gases inside it on its incompletely hardened surface.

BLOCKING—An undesired adhesion between touching layers of a material, such as occurs under moderate pressure during storage or use.

BLOOM—See *Lubricant Bloom*.

BLOW MOLDING—Method of producing hollow plastic objects by stretching and hardening softened plastic material against a mold through the application of pressure, usually by compressed air.

BLOWING AGENTS—See *Foaming Agents*.

BODY (n.)—A qualitative indication of the viscosity of oil, varnish, or paint; "heavy body" denotes a relatively high viscosity and "light body" a relatively low viscosity. (v.)—To increase the viscosity of an oil by heat treatment or by other means.

BOSS—Protuberance on a plastic part designed to add strength, to facilitate alignment during assembly, to provide for fastenings, etc.

BRANCHED—In molecular structure of polymers (as opposed to *Linear*), refers to side chains attached to the main chain. Side chains may be long or short.

BREAKER PLATE—A perforated plate located to the rear of the die in an extruder. It supports the screens that prevent foreign particles from entering the die. Also *Screen Plate*.

BREATHING—The opening and closing of a mold to allow gases to escape early in the molding cycle. Also called *degassing*. When referring to plastic sheeting, "breathing" indicates permeability to air.

BULK DENSITY—The mass per unit volume of a molding powder as determined in a reasonably large volume. The recommended test method is ASTM D1182-54.

BULK FACTOR—The ratio of the volume of loose molding powder to the volume of the finished molded article.

C

C-STAGE—The final stage in the reactions of a thermosetting resin in which the material is relatively insoluble and infusible. Thermosetting resins in a fully cured plastic are in this stage. See *A-Stage* and *B-Stage*.

CALENDER (*v.*)—To prepare sheets of material by pressure between two or more revolving rolls. (*n.*)—The machine performing this operation.

CAPROLACTAM—A cyclic amide-type compound, containing 6 carbon atoms. When the ring is opened, caprolactam is polymerizable into a nylon resin known as type-6 nylon or polycaprolactam.

CASEIN—A protein material precipitated from skimmed milk by the action of either rennet or dilute acid.

Rennet casein finds its main application in the manufacture of plastics. Acid casein is a raw material used in a number of industries including the manufacture of adhesives.

CAST—To form a plastic material into a certain shape by pouring it into a mold and letting it harden without applying external pressure. Also applies to forming plastic film and sheet by pouring the liquid resin onto a moving belt or by precipitation in a chemical bath.

CASTING—The finished product of a casting operation; should not be used for *molding*, q.v.

CATALYST—A substance which markedly speeds up the cure of a compound when added in minor quantity as compared to the amounts of primary reactants. See also *Hardener* and *Inhibitor*.

CAVITY—Depression in a mold made by casting, machining, hobbing, or a combination of these methods; depending on number of such depressions, molds are designated as *Single-Cavity or Multi-Cavity*.

CELLULAR PLASTICS — See *Foamed Plastics*.

CELLULOID—A thermoplastic material made by the intimate blending of cellulose nitrate q.v., with camphor. Alcohol is normally employed as a volatile solvent to assist plasticization, and is subsequently removed.

CELLULOSE — Inert substance, chemically a carbohydrate, which makes up the solid structure of plants.

CELLULOSE ACETATE—An acetic acid ester of cellulose. It is obtained by the action, under rigidly controlled conditions, of acetic acid and acetic anhydride on purified cellulose usually obtained from cotton linters. All three available hydroxyl groups in each glucose unit of the cellulose can be acetylated but in the material normally used for plastics it is usual to acetylate fully and then to lower the acetyl value (expressed as acetic acid) to 52-56% by partial hydrolysis. When compounded with suitable plasticizers it gives a tough thermoplastic material.

CELLULOSE ACETATE BUTYRATE—An ester of cellulose made by the action of a mixture of acetic and butyric acids and their anhydrides on purified cellulose.

It is used in the manufacture of plastics which are similar in general properties to cellulose acetate but are tougher and have better moisture resistance and dimensional stability.

CELLULOSE ESTER—A derivative of cellulose in which the free hydroxyl groups attached to the cellulose chain have been replaced wholly or in part by acidic groups, e.g., nitrate, acetate, or stearate groups. Esterification is effected by the use of a mixture of an acid with its anhydride in the presence of a catalyst, such as sulfuric acid. Mixed esters of cellulose, e.g., cellulose acetate butyrate, are prepared by the use of mixed acids and mixed anhydrides. Esters and mixed esters, a wide range of which is known, differ in their compatibility with plasticizers, in molding properties, and in physical characteristics.

These esters and mixed esters are used in the manufacture of thermoplastic molding compositions.

CELLULOSE NITRATE (Nitrocellu-

lose)—A nitric acid ester of cellulose manufactured by the action of a mixture of sulfuric acid and nitric acid on cellulose, such as purified cotton linters. The type of cellulose nitrate used for celluloid manufacture usually contains 10.8-11.1% of nitrogen. The latter figure is the nitrogen content of the dinitrate.

CELLULOSE PROPIONATE—An ester of cellulose made by the action of propionic acid and its anhydride on purified cellulose. It is used as the basis of a thermoplastic molding material.

CENTRIFUGE—A rotating device for separating solids from liquids or liquids of markedly different specific gravities.

CHAIN LENGTH—See *Degree Of Polymerization.*

CHARGE—The measurement or weight of material used to load a mold at one time or during one cycle.

CHASE—An enclosure of any shape, used to: a) shrink-fit parts of a mold cavity in place; b) prevent spreading or distortion in hobbing; c) enclose an assembly of two or more parts of a split cavity block.

CHLOROPRENE—A 2-chloro-1, 3-butadiene—a colorless liquid which will polymerize to polychloroprene (neoprene).

CHROME-PLATED MOLDS—Hard chromium plating is applied to molds to provide corrosion and abrasion resistance and a low coefficient of friction.

CLAMPING PLATE—A plate fitted to a mold and used to fasten the mold to a molding machine.

CLAMPING PRESSURE—In injection molding and in transfer molding, the pressure which is applied to the mold to keep it closed, in opposition to the fluid pressure of the compressed molding material.

COEFFICIENT OF EXPANSION—Ratio of increase in length, area, or volume of a substance for a unit temperature rise.

COLD FLOW—See *Creep.*

COLD MOLDING—A procedure in which a composition is shaped at room temperature and cured by subsequent baking.

COLD PRESSING—A bonding operation in which an assembly is subjected to pressure without the application of heat.

COLD SLUG—The first material to enter an injection mold; so called because in passing through sprue orifice it is cooled below the effective molding temperature.

COLD SLUG WELL—Space provided directly opposite the sprue opening in an injection mold to trap the cold slug.

COLD STRETCH—Pulling operation, usually on extruded filaments, to improve tensile properties.

COLLOID—Any substance in a state of fine dispersion, with particles having size range between 5 and 100 millimicrons. Molecules of many synthetic resins fall within this range.

COMPRESSION MOLD—A mold which is open when the material is introduced and which shapes the material by heat and by the pressure of closing.

COMPRESSION MOLDING—A technique of thermoset molding in which the molding compound (generally preheated) is placed in the open mold cavity, mold is closed, and heat and pressure (in the form of a downward moving ram) are applied until the material has cured.

COMPRESSIVE STRENGTH—Crushing load at the failure of a specimen divided by the original sectional area of the specimen.

CONDENSATION—A chemical reaction in which two or more molecules combine with the separation of water or some other simple substance. If a polymer is formed, the condensation process is called *Polycondensation.* See also *Polymerization.*

CONDENSATION RESIN—A resin formed by polycondensation, e.g., the alkyd, phenol-aldehyde, and urea formaldehyde resins.

CONTACT PRESSURE RESINS—Liquid resins which thicken or resinify on heating and, when used for bonding laminates, require little or no pressure.

COOLING FIXTURE—Block of metal or wood holding the shape of a molded piece which is used to maintain the proper shape or dimensional accuracy of a molding after it is removed from the mold until it is cool enough to retain its shape without further appreciable distortion. Also known as *Shrink Fixture.*

COPOLYMER—See *Polymer.*

CORE—The central member of a sandwich construction (can be honeycomb material, foamed plastic, or solid sheet) to which the faces of the sandwich are attached; the central member of a plywood assembly.

CORE PIN—A pin for forming a hole or opening in a molded piece.

COVER MOLD—The stationary half of an injection mold; also called *Front Mold.*

CRAZING—Fine cracks which may extend in a network on or under the surface or through a layer of a plastic material.

CREEP—The dimensional change with time of a material under load, following the initial instantaneous elastic deformation. Creep at room temperature is sometimes called *Cold Flow.*

CROSS LAMINATED—Laminated so that some of the layers of material are oriented at right angles to the remaining layers with respect to the grain or strongest direction in tension. Normally balanced construction of the laminations about the center line of the thickness of the laminate is assumed. See *Parallel Laminated.*

CROSS-LINK—Tying together large molecules (and, hence, changing the physical properties of a material), accomplished by radiation or other means.

CULL—Material remaining in a transfer chamber after mold has been filled. Unless there is a slight excess in the charge, the operator cannot be sure cavity is filled. Charge is generally regulated to control thickness of cull.

CURE—To change the physical properties of a material by chemical reaction, which may be condensation, polymerization, or vulcanization; usually accomplished by the action of heat and catalysts, alone or in combination, with or without pressure.

CURING TEMPERATURE—Temperature at which a cast, molded, or extruded product, a resin-impregnated reinforcing material, an adhesive, etc., is subjected to curing.

CURING TIME (Molding Time)—In the molding of thermosetting plastics. The interval of time between the instant of cessation of relative movement between the moving parts of a mold and the instant that pressure is released.

CUT-OFF—The line where the two halves of a mold come together; also called a *Land* or *Flash Ridge, Flash Groove.*

CYCLE—One complete operation of

a molding press from closing time to closing time.

D

DAYLIGHT OPENING—Clearance between two platens of a press in the open position.

DECORATIVE SHEET—A laminated plastics sheet used for decorative purposes in which the color and/or surface pattern is an integral part of the sheet.

Standards of quality for certain types of synthetic resin-bonded-paper sheet for decorative purposes are given in B.S. 1323 "Synthetic resin-bonded-paper sheet (thermosetting) for use in the building industry."

DEGASSING—See *Breathing*

DEGREE OF POLYMERIZATION (DP)—The number of structural units or mers in the "average" polymer molecule in a particular sample. In most plastics the DP must reach several thousand if worthwhile physical properties are to be had.

DELAMINATE—To split a laminated plastic material along the plane of its layers; see *Laminate*.

DELAMINATION—The separation of layers in a laminate because of failure of the adhesive.

DENIER—A unit of yarn number. The number of grams per 9000 meters length.

DENSITY—Weight per unit volume of a substance, expressed in grams per cubic centimeter, pounds per cubic foot, etc.

DESICCANT—Substance which can be used for drying purposes because of its affinity for water.

DESTATICIZATION—Treating plastics materials to minimize their accumulation of static electricity and, consequently, the amount of dust picked up by the plastics because of such charges.

DIELECTRIC—Insulating material. In radio-frequency preheating, dielectric may refer specifically to the material which is being heated.

DIELECTRIC CONSTANT—Normally the relative dielectric constant; for practical purposes, the ratio of the capacitance of an assembly of two electrodes separated solely by a plastics insulating material to its capacitance when the electrodes are separated by air (ASTM Dl50-54T).

DIELECTRIC HEATING (Electronic heating)—Heating produced by dielectric loss.

DIELECTRIC STRENGTH—The ability of an insulating material to resist the passage of a disruptive discharge produced by an electric stress.

DIMENSIONAL STABILITY—Ability of a plastic part to retain the precise shape in which it was molded, fabricated, or cast.

DIP COATING—Deposition of a plastic coating on any article (for purposes of protection or decoration) by means of a simple dipping operation.

DISCOLORATION — Any change from an initial color possessed by a plastic; a lack of uniformity in color where color should be uniform over the whole area of a plastic object. In the latter sense, where they can be applied, use the more definite terms *Mottle, Segregation,* or *Two-Tone*.

DISPERSION—Finely divided particles of a material in suspension in another substance.

DISSIPATION FACTOR — See *Power Factor*.

DOUBLE-SHOT MOLDING—A means of turning out two-color parts in thermoplastics materials by successive injection molding operations.

DRAFT—The degree of taper of a side wall or the angle of clearance designed to facilitate removal of parts from a mold.

DRAPE ASSIST FRAME—In sheet thermoforming, a frame (made up of anything from thin wires to thick bars) shaped to the peripheries of the depressed areas of the mold and suspended above the sheet to be formed. During forming, the assist frame drops down drawing the sheet tightly into the mold and thereby preventing webbing between high areas of the mold and permitting closer spacing in multiple molds.

DRAPE FORMING—Method of forming thermoplastic sheet in which the sheet is clamped into a movable frame, heated, and draped over high points of a male mold. Vacuum is then pulled to complete the forming operation.

DRAWING—The process of stretching a thermoplastic sheet or rod to reduce its cross-sectional area.

DRY COLORING—Method commonly used by fabricators for coloring plastics by tumble blending crystal particles of the plastic with selected dyes and pigments.

DRY STRENGTH—The strength of an adhesive joint determined immediately after drying under specified conditions or after a period of conditioning in the standard laboratory atmosphere. See *Wet Strength*.

DRYING OIL—A special type of oil, such as tung or perilla, which hardens readily when exposed to the air; used as an ingredient in varnishes.

DUPLICATING—Milling operation in which the contour or outline to be milled is followed by a tracer or stylus that governs the motion of one or more cutting spindles.

DWELL—A pause in the application of pressure to a mold, made just before the mold is completely closed, to allow the escape of gas from the molding material.

E

EJECTOR PIN—A device that knocks a finished piece out of the mold.

EJECTOR PIN ASSEMBLY—All the parts that help to knock the finished piece from a mold. In some designs, it also frees split parts or loose pieces from mold cavities.

EJECTOR PIN PLATE—A plate which supports ejector pins and holds ejector assembly together.

EJECTOR RETURN PINS—Projections that push the ejector assembly back as the mold closes; also called *Surface Pins* and *Return Pins*.

EJECTOR ROD—Bar that actuates the ejector assembly when mold is opened.

ELASTOMER—A material which at room temperature can be stretched repeatedly to at least twice its original length and, upon immediate release of the stress, will return with force to its approximate original length.

ELECTRIC STRENGTH (Dielectric Strength)—1) That property of an insulating material which enables it to withstand electric stress. 2) The highest electric stress which an insulating material can withstand for a specified time without the occurrence of electrical breakdown by any path through its bulk. Its value is given by the potential difference in volts

divided by the thickness of a test specimen in thousandths of an inch, i.e. in volts per mil (ASTM D149-55T). 3) The highest potential difference which a specimen of insulating material of given thickness can withstand for a specified time without the occurrence of electrical breakdown by any path through its bulk.

ELECTROFORMED MOLDS—A mold made by electroplating metal on the reverse pattern on the cavity. Molten steel may be then sprayed on the back of the mold to increase its strength.

ELONGATION—The increase in length of a material when it is subjected to tensile stress. It is expressed as a fraction of the original length.

EMULSION—A suspension of fine droplets of one liquid in another.

ENCAPSULATING—Enclosing an article (usually an electronic component or the like) in a closed envelope of plastic, by immersing the object in a casting resin and allowing the resin to polymerize or, if hot, to cool.

EPOXY RESINS—Based on ethylene oxide, its derivatives or homologs, epoxy resins form straight-chain thermoplastics and thermosetting resins, e.g., by the condensation of bisphenol and epichlorohydrin.

ESTER—The reaction product of an alcohol and an acid.

EXOTHERM—1) The temperature/time curve of a chemical reaction giving off heat, particularly the polymerization of casting resins. 2) The amount of heat given off. The term has not been standardized with respect to sample size, ambient temperature, degree of mixing, etc.

EXOTHERMIC—An adjective describing chemical reactions that give off heat to the surroundings. If this heat is not removed, the temperature of the reacting mass keeps rising until the reaction is complete.

EXPANDED PLASTICS — See *Foamed Plastics*

EXTENDER—A substance, generally having some adhesive action, added to a plastic composition to reduce the amount of the primary resin required per unit area.

EXTRUDATE—The product or material delivered by an extruder, such as film, pipe, the coating on wire, etc.

EXTRUSION—The compacting of a plastic material and the forcing of it through an orifice in more or less continuous fashion.

F

FABRICATE—To work a material into a finished form by machining, forming, or other operation or to make flexible film or sheeting into end-products by sewing, cutting, sealing, or other operation.

FILAMENT—A variety of fiber characterized by extreme length, which permits its use in yarn with little or no twist and usually without the spinning operation required for fibers.

FILLER—A cheap, inert substance added to a plastic to make it less costly. Fillers may also improve physical properties, particularly hardness, stiffness, and impact strength. The particles are usually small, in contrast to those of reinforcements (q.v.), but there is some overlap between the functions of the two.

FILLER-SPECKS—Visible specks of woodflour, asbestos, or other filler, which stand out in contrasting color against a plastic binder.

FILLET—A rounded filling of the internal angle between two surfaces of a plastic molding.

FILM—An optional term for sheeting having a nominal thickness not greater than 0.010 inch.

FIN—The web of material remaining in holes or openings in a molded part which must be removed in finishing.

FINES—Pulverized particles of materials accompanying larger grains or fibers.

FLAME SPRAYING—Method of applying a plastic coating in which finely powered fragments of the plastic, together with suitable fluxes, are projected through a cone of flame onto a surface.

FLAKE—Used to denote the dry, unplasticized base of cellulosic plastics.

FLAMMABILITY—Measure of the extent to which a material will support combustion.

FLASH — Excess plastic material which forms at the parting line during molding, and which must be removed from the finished article.

FLASH LINE—A raised line appearing on the surface of a molding and formed at the junction of mold faces.

FLASH MOLD—A mold designed to permit excess molding material to escape during closing.

FLEXIBLE MOLDS—Molds made of rubber or elastomeric plastics used for casting plastics. They can be stretched to remove cured pieces with undercuts.

FLEXIBLE RESIN—A resin that is, in comparison with others under consideration, less stiff. Loosely, any material in which the modulus of elasticity is so low that it is of no practical importance.

FLEXIBILIZER—An additive that makes a resin or rubber more flexible, i.e., less stiff. Also a plasticizer.

FLEXURAL STRENGTH—Ability of a material to withstand failure due to bending.

FLOATING PLATEN—A platen located between the main head and the press table in a multi-daylight press and capable of being moved independently of them.

FLOW—A qualitative description of the fluidity of a plastic material during the process of molding.

FLOW LINE (Weld Line)—A line on the surface of a molding corresponding to an area of discontinuity within the molding due to partial hardening of material before flow has finally ceased.

FLOW MARK—A mark on a molding caused by the flow of partially hardened molding material along the surface of the mold.

FOAMED PLASTICS—Resinous materials that have been expanded into a multicellular structure characterized by low density and relatively high strength. Used as a core material in sandwich structures, as an insulating material, as cushioning, etc.

FOAMING AGENTS—Chemical additives for plastics and rubber that decompose on heating, yielding gases which produce lightweight cellular products, e.g., foamed plastics.

FORCE PLATE—The plate that carries the plunger or force plug of a mold and guide pins or bushings. Since it is usually drilled for steam or water lines, it is also called the *Steam Plate*.

FORCE PLUG—The portion of a mold that enters the cavity block and exerts pressure on the mold-

ing compound, designated as *Top Force* or *Bottom Force* by position in the assembly; also called *Plunger* or *Piston*.

FULLY AUTOMATIC PRESS—A hydraulic press for compression molding, or an injection molding machine, which operates continuously, the timing of the operations being controlled mechanically, electrically, hydraulically, or by a combination of these methods.

FURAN RESINS—Dark colored, thermosetting resins available primarily as liquids ranging from low-viscosity polymers to thick, heavy sirups.

FUSION—The operation of liquefying or combining materials by means of heat.

G

GATE—The short, restricted section of the runner at entrance to an injection mold cavity.

GEL (*n.*)—A semi-solid system consisting of a network of solid aggregates in which liquid is held.

GELATION—Process of turning a flowable liquid into a nonflowing jelly. This may be accomplished by addition or precipitation of a solforming agent, by chilling, or by evaporating solvent.

GEL COAT—A thin, outer layer of resin, sometimes containing pigment, applied to a reinforced plastics molding as a cosmetic.

GRANULAR STRUCTURE—Nonuniform appearance of finished plastic material due to retention of, or incomplete fusion of, particles of composition, either within the mass or on the surface.

GRIDS—Parallel channel-shaped cast iron supports that hold the steam plates away from the press platens during knockout operation and also provide air spaces between plates and platens to reduce loss of heat.

GUIDE PINS—Devices that maintain proper alignment of force plug and cavity as mold closes.

GUM (*n.*)—Any of a class of colloidal substances, exuded by or prepared from plants, sticky when moist, composed of complex carbohydrates and organic acids, which are soluble or swell in water. The term *Gum* is sometimes used loosely to denote various materials that exhibit gummy characteristics under certain conditions, i.e., gum balata, gum benzoin, and gum asphaltum. Gums are included by some in the category of natural resins.

H

HAND—The texture or feel of a fabric.

HARDENER—A substance or mixture of substances added to plastic composition, or an adhesive to promote or control the curing reaction by taking part in it. The term is also used to designate a substance added to control the degree of hardness of the cured film. See also *Catalyst*.

HEAT DISTORTION POINT—The temperature at which a standard bar of plastic material will be deflected 0.010 inch.

HEAT MARK—An extremely shallow, regular, or irregular depression or groove in the surface of a plastic visible only because of a sharply defined rim or a roughened surface.

HEAT-SEAL—To bond or weld a material (usually flexible film or sheeting) to itself or to another material by heat alone. Heating methods usually employed are dielectric, electronic, or inductive.

HEATING CHAMBER—In injection and transfer molding, that part of the machine in which the cold feed is reduced to a hot melt.

HEATING CYLINDER (Heating chamber, Feed cylinder)—The chamber of an injection molding machine wherein materials are plasticated by heat before being injected into the mold. This chamber may be constructed of stainless steel and may be heated by electrical or other means.

H. F. PREHEATING—A process in which a rapidly alternating electric field (20 to 80 mc.) is applied to a plastic, usually a thermoset, in order to bring it up to the molding temperature. Heating depends on dielectric loss in the resin and is fast and uniform.

HIGH-PRESSURE LAMINATES—Laminates molded and cured at pressures not lower than 1000 p.s.i. and more commonly in the range of 1200 to 2000 p.s.i.

HOB—A master model in hardened steel used to sink the shape of a mold into a soft steel block.

HOBBING—A process of forming a mold cavity by forcing a hardened steel master model of the shape desired into a soft steel cavity blank which is then trimmed to size, hardened, and polished.

HONEYCOMB—Manufactured product consisting of sheet metal or a resin-impregnated sheet material (paper, fibrous glass, etc.) which has been formed into hexagonal-shaped cells. Used as core material for sandwich constructions.

HOPPER—Receptacle located at the top of a molding machine into which plastic material is placed and from which it is metered into the heating chamber of the machine.

HOPPER DRYER—A combination feeding and drying device for extrusion and injection molding of thermoplastics. Hot air flows upward through the hopper containing the feed pellets.

HOT-MELT COATING—Applying a thermoplastic coating when it is heated and consequently in a fluid state. (Also *Dip Coating*.)

HOT-RUNNER MOLDS—A mold in which material in the runners of the mold are always in a plasticated condition.

HOT-STAMPING—Engraving operation for marking plastics in which roll leaf is stamped with heated metal dies onto the face of the plastics. Ink compounds can also be used. By means of felt rolls, ink is applied to type and by means of heat and pressure, type is impressed into the material, leaving the marking compound in the indentation.

HUB—Word frequently used for *Hob*. See *Hobbing*.

HYDROGENATION — Chemical process whereby hydrogen is introduced into a compound.

HYDROLYSIS—Chemical decomposition of a substance involving the addition of water.

HYDROLYZE.—To undergo *Hydrolysis*.

HYDROPHILIC—Possessing strong affinity for water.

HYDROPHOBIC—Lacking strong affinity for water.

HYGROSCOPIC—Tending to absorb moisture.

I

IMPACT RESISTANCE—Relative susceptibility of plastics to fracture by shock, e.g., as indicated by

the energy expended by a standard pendulum type impact machine in breaking a standard specimen in one blow.

IMPACT STRENGTH—1) The ability of a material to withstand shock loading. 2) The work done in fracturing, under shock loading, a specified test specimen in a specified manner.

INDEX OF REFRACTION—The ratio of the velocity of light in a vacuum to its velocity in the substance; the ratio of the sine of the angle of incidence to the sine of the angle of refraction.

INFRA-RED—Zone of invisible radiations below the red end of the spectrum of visible radiations. Waves are longer and more penetrating than those of light; zone is characterized by heat.

INHIBITOR—A substance that slows down chemical reaction. Inhibitors are sometimes used in certain types of monomers and resins to prolong storage life.

INJECTION MOLD—A mold into which a plasticated material is introduced from an exterior heating cylinder.

INJECTION MOLDING—A molding procedure whereby a heat-softened plastic material is forced from a cylinder into a relatively cool cavity which gives the article the desired shape.

INJECTION PRESSURE—The pressure on the face of the injection ram at which molding material is injected into a mold. It is usually expressed in p.s.i.

INJECTION RAM—The ram which applies pressure to the plunger in the process of injection molding or transfer molding.

INSERT—An integral part of a plastics molding consisting of metal or other material which may be molded into position or may be pressed into the molding after the molding is completed.

INTERCONNECTING—Applies to open-cell foamed plastics materials.

INTRINSIC VISCOSITY—The intrinsic viscosity of a polymer is the limiting value at infinite dilution of the ratio of the specific viscosity of the polymer solution to its concentration in moles per liter.

$$\eta_i = \underset{c \to 0}{\text{Lim}} \frac{\eta_{sp}}{c}$$

where η_i = intrinsic viscosity, η_{sp} = specific viscosity, c = concentration in moles per liter. Intrinsic viscosity is usually estimated by determining the specific viscosity at several low concentrations and extrapolating the values of $\frac{\eta_{sp}}{c}$ to c = 0. The concentration is expressed in terms of the repeating unit. In the case of polystyrene the repeating unit is $-CH_2-CH(C_6H_5)-$ and has a molecular weight of 104.

ION EXCHANGE RESINS—Small granular or bead-like particles containing acidic or basic groups, which will trade ions with salts in solutions. Generally used for softening and purifying water.

IRRADIATION (ATOMIC)—As applied to plastics, refers to bombardment with a variety of subatomic particles, generally alpha-, beta-, or gamma-rays. Atomic irradiation has been used to initiate polymerization and copolymerization of plastics and in some cases to bring about changes in the physical properties of a plastic material.

J

JACKET—An enveloping hollow metal cover for holding circulating steam or water used to heat or cool the mechanism it covers (such as a mixing vessel, mold, or platen).

JET MOLDING—Processing technique characterized by the fact that most of the heat is applied to the material as it passes through the nozzle or jet, rather than in a heating cylinder as is done in conventional processes.

JIG—Tool for holding component parts of an assembly during the manufacturing process, or for holding other tools. Also called a *Fixture*.

K

KNIT LINES—See *Weld Mark*.

KNOCKOUT PIN—A device for knocking a cured piece from a mold. Also called *Ejector Pin*.

L

LACQUER—Solution of natural or synthetic resins, etc., in readily evaporating solvents, which is used as a protective coating.

LAMINATED PLASTICS (Synthetic Resin-Bonded Laminate, Laminate)—A plastics material consisting of superimposed layers of a synthetic resin-impregnated or -coated filler which have been bonded together, usually by means of heat and pressure, to form a single piece.

LAMINATED WOOD—A bonded wood product composed of layers of wood. This generic term covers all orientations of grain of the various layers of wood. The term *Plywood* covers a form of laminated wood in which successive layers of veneer are ordinarily cross laminated, the core of which may be veneer or sawn lumber in one piece or several pieces. See *Cross Laminated*, *Parallel Laminated*, and *Plywood*.

LAMINATION—The process of preparing a laminate. Also any layer in a laminate.

LAND—The horizontal bearing surface of a semi-positive or flash mold by which excess material escapes. See *Cut-off*.

LATEX—Milky rubber-containing exudation of certain trees; aqueous dispersion of an elastomeric resin.

LAY-UP (*n.*)—As used in reinforced plastics, the reinforcing material placed in position in the mold; also the resin-impregnated reinforcement. (*v.*)—The process of placing the reinforcing material in position in the mold.

LEACH—To dissolve a substance out of another by percolation.

LIGNIN—A naturally occurring resin found in wood and other vegetation as the binding agent for the cellulosic structure.

LINEAR MOLECULE—A long chain molecule as contrasted to one having many side chains or branches.

LINTERS—Short fibers that adhere to the cotton seed after ginning. Used in rayon manufacture, as fillers for plastics, and as a base for the manufacture of cellulosic plastics.

LOADING TRAY (Charging tray)—A device in the form of a specially designed tray which is used to load the charge simultaneously into each cavity of a multi-cavity mold by the withdrawal of a sliding bottom from the tray.

LOSS FACTOR—The product of the power factor and the dielectric constant.

LOW PRESSURE LAMINATES—In

general, laminates molded and cured in the range of pressures from 400 p.s.i. down to and including pressures obtained by the mere contact of the plies.

LUBRICANT BLOOM—An irregular, cloudy, greasy film on a plastic surface.

M

MACERATE — Any chopped or shredded fabric used as a filler for a molding compound. A *molded macerate* is a variant of a molded laminate and intermediate between molded laminates and powder moldings.

MACROMOLECULE—The large ("giant") molecules which make up the high polymers.

MANDREL—The core or spindle around which paper or fabric is wound to form laminated tubes or around which resin-impregnated fibrous glass is wound to form pipe or tube.

MAT—A jackstraw arrangement of fine glass fibers uniformly distributed to form a thin, highly porous, felt-like material.

MATERIAL WELL—Space provided in a compression or transfer mold to care for bulk factor.

MATCHED METAL MOLDING—Method of molding reinforced plastics between two close-fitting metal molds mounted in a hydraulic press.

MECHANICAL ADHESION—Adhesion between surfaces in which the adhesive holds the parts together by interlocking action. See also *Specific Adhesion*.

METALIZING—Applying a thin coating of metal to a nonmetallic surface. May be done by plating or vacuum pressure.

MELAMINE FORMALDEHYDE RESIN—Classified as a synthetic resin derived from the reaction of melamine (2,4,6-triamino-1,3,5, triazine) with formaldehyde or its polymers.

MIGRATION OF PLASTICIZER—Loss of plasticizer from an elastomeric plastic compound with subsequent absorption by an adjacent medium of lower plasticizer concentration.

MODIFIED WOOD—Any wood the properties of which have been improved by chemical, thermal, and/or compression treatment.

MODULUS OF ELASTICITY—The ratio of unit stress to unit strain.

MOLD (*v.*)—To shape plastic parts or finished articles by heat and pressure. (*n.*)—1) The cavity or matrix into which the plastic composition is placed and from which it takes its form. 2) The assembly of all the parts that function collectively in the molding process.

MOLDING—Sometimes used to denote finished piece.

MOLDING CYCLE—1) The period of time occupied by the complete sequence of operations on a molding press requisite for the production of one set of moldings. 2) The operations necessary to produce a set of moldings without reference to the time taken.

MOLDING POWDER—Plastic material in varying stages of granulation, and comprising resin, filler, pigments, plasticizers, and other ingredients, ready for use in the molding operation.

MOLDING PRESSURE—The pressure applied to the ram of an injection machine or press to force the softened plastic completely to fill the mold cavities.

MOLDING SHRINKAGE (Mold Shrinkage, Shrinkage, Contraction)—The difference in dimensions, expressed in inches per inch, between a molding and the mold cavity in which it was molded, both the mold and the molding being at normal room temperature when measured.

MONOFILAMENT (Monofil)—A single filament of indefinite length. Monofilaments are generally produced by extrusion. Their outstanding uses are in the fabrication of bristles, surgical sutures, fishing leaders, tennis-racquet strings, screen materials, ropes and nets; the finer monofilaments are woven and knitted on textile machinery.

MONOMER—A relatively simple compound which can react to form a polymer. See also *Polymer*.

MULTI-CAVITY MOLD—A mold with two or more mold impressions, i.e., a mold which produces more than one molding per molding cycle.

N

NEST PLATE—A retainer plate with a depressed area for cavity blocks used in injection molding.

NONPOLAR—Having no concentrations of electrical charge on a molecular scale, thus, incapable of significant dielectric loss. Examples among resins are polystyrene and polyethylene.

NON-RIGID PLASTIC—A nonrigid plastic is one which has a stiffness or apparent modulus of elasticity of not over 50,000 p.s.i. at 25° C. when determined according to ASTM test procedure D747-43 T.

NOTCH SENSITIVITY—The extent to which the sensitivity of a material to fracture is increased by the presence of a surface inhomogeneity such as a notch, a sudden change in section, a crack, or a scratch. Low notch sensitivity is usually associated with ductile materials, and high notch sensitivity with brittle materials.

NOVOLAK—A phenolic-aldehyde resin which, unless a source of methylene groups is added, remains permanently thermoplastic. See also *Resinoid* and *Thermoplastic*.

NOZZLE—The hollow cored metal nose screwed into the extrusion end of *a*) the heating cylinder of an injection machine or *b*) a transfer chamber where this is a separate structure. A nozzle is designed to form under pressure a seal between the heating cylinder or the transfer chamber and the mold. The front end of a nozzle may be either flat or spherical in shape.

NYLON—The generic name for all synthetic fiber-forming polyamides; they can be formed into monofilaments and yarns characterized by great toughness, strength and elasticity, high melting point, and good resistance to water and chemicals. The material is widely used for bristles in industrial and domestic brushes, and for many textile applications; it is also used in injection molding gears, bearings, combs, etc.

O

OIL-SOLUBLE RESIN — Resin which at moderate temperatures will dissolve in, disperse in, or react with, drying oils to give a homogeneous film of modified characteristics.

ORANGE-PEEL—Uneven surface somewhat resembling an orange peel.

ORGANOSOL—A vinyl dispersion,

the liquid phase of which contains organic volatile liquids. See also *Plastisols.*

OVERLAY SHEET (Surfacing Mat)—A non-woven fibrous mat (either in glass, synthetic fiber, etc.) used as the top layer in a cloth or mat lay-up to provide a smoother finish or minimize the appearance of the fibrous pattern.

P

PANTOGRAPH—A duplicating machine used for engraving of plastics as well as mold components. Most pantographs are equipped with a variable reducing feature permitting the work to be smaller than the model while retaining relative dimensions.

PARALLEL LAMINATED—Laminated so that all the layers of material are oriented approximately parallel with respect to the grain or strongest direction in tension. See also *Cross Laminated.*

PARALLELS—1) Spacers placed between the steam plate and press platen to prevent the middle section of the mold from bending under pressure. 2) Pressure pads or spacers between the steam plates of a mold to control height when closed and to prevent crushing the parts of the mold when the land area is inadequate.

PARTING AGENT—A lubricant, often wax, used to coat a mold cavity to prevent the molded piece from sticking to it, and thus to facilitate its removal from the mold. Also called *Release Agent.*

PARTING LINE—Mark on a molding or casting where halves of mold met in closing.

PASTE—An adhesive composition having a characteristic plastic-type consistency, i.e., a high order of yield value, such as that of a paste prepared by heating a mixture of starch and water and subsequently cooling the hydrolized product.

PERMANENT SET—The increase in length, expressed in a percentage of the original length, by which an elastic material fails to return to original length after being stressed for a standard period of time.

PERMEABILITY—1) The passage or diffusion of a gas, vapor, liquid, or solid through a barrier without physically or chemically affecting it. 2) The rate of such passage.

pH—The measure of the acidity or alkalinity of a substance, neutrality being at pH 7. Acid solutions are under 7, alkaline solutions over 7.

PHENOLIC RESIN—1) A synthetic resin produced by the condensation of a phenol with an aldehyde.

2) A synthetic resin produced by the condensation of phenol (hydroxybenzene) with formaldehyde.

Phenolic resins form the basis of thermosetting molding materials, laminated sheet, and stoving varnishes. They are also used as impregnating agents and as components of paints, varnishes, lacquers, and adhesives.

PILL—See *Preform.*

PITCH—A dark-colored, fusible, more or less viscous to solid bituminous or resinous substance.

PLASTIC (*a.*)—Capable of being molded; made of any type of *Plastics.* (*n.*)—A plastic is any one of a large and varied group of materials which consists of, or contains as an essential ingredient, a substance of high molecular weight, and which, while solid in the finished state, at some stage in its manufacture is soft enough to be formed (cast, calendered, extruded, molded, etc.) into shape by flow—usually through the application singly or together of heat and pressure.

PLASTIC FLOW—Flow which is proportional to the pressure in excess of a certain minimum pressure (yield value) necessary to start the flow.

PLASTIC TOOLING—Tools, e.g. dies, jigs, fixtures, etc., for the of plastics, generally laminates or metal forming trades constructed casting materials.

PLASTICATE—To soften by heating or kneading. Synonyms are: plastify, flux, and, (imprecisely) plasticize (q.v.).

PLASTICITY—The property of solids by virtue of which they can be made to take and retain the form of a mold.

PLASTICIZE—To soften a material and make it plastic or moldable, either by means of a plasticizer or the application of heat.

PLASTICIZER—Chemical agent added to plastic compositions to make them softer and more flexible.

PLASTIGEL—A plastisol exhibiting gel-like flow properties.

PLASTISOLS—Mixtures of resins and plasticizers which can be molded, cast, or converted to continuous films by the application of heat. If the mixtures contain volatile thinners also, they are known as *Organosols.*

PLATENS—The mounting plates of a press to which the entire molding assembly is bolted.

PLUG-AND-RING — Method of sheet forming in which a plug, functioning as a male mold, is forced into a heated plastic sheet held in place by a clamping ring.

PLUNGER—See *Force Plug.*

PLYWOOD—A bonded wood product composed of laminated veneers, in which the grain of the layers of veneer are arranged in a nonparallel orientation; the usual arrangement is with the grain of successive plies at right angles.

POLAR—See *Nonpolar.*

POLYAMIDE—A polymer in which the structural units are linked by amide or thio-amide groupings. Many polyamides are fiber-forming.

POLYCONDENSATION—See *Condensation.*

POLYESTER—A resin composed of polymeric esters in which the recurring ester groups are an integral part of the main polymer chain. Unsaturated polyesters contain carbon double bonds which permit cross-linking and hence conversion of the resin to a substantially infusible and insoluble product.

POLYETHYLENE (Polythene)—A thermoplastic material composed of polymers of ethylene. It is normally a translucent, tough, waxy solid which is unaffected by water and by a large range of chemicals. It is a particularly good insulating material with low power factor and low dielectric constant, high resistivity, and high dielectric strength. An outstanding application is in cable manufacture. It is also applied in such uses as chemical plant, packaging, and for decorative purposes.

POLYISOBUTYLENE—The polymerization product of isobutylene. It varies in consistency from a viscous liquid to a rubber-like solid with corresponding variation in molecular weight from 1000 to 400,000.

POLYLINER—A perforated longi-

tudinally ribbed sleeve that fits inside the cylinder of an injection molding machine; used as a replacement for conventional injection cylinder torpedos.

POLYMER—A compound formed by the linking of simple molecules having functional groups which permit their combination to proceed to high molecular weights under suitable conditions. Polymers may be formed by polymerization (addition polymer) or by polycondensation (condensation polymer). When two or more monomers are involved, the reaction product is a copolymer.

POLYMERIZATION—A chemical reaction in which the molecules of a monomer are linked together to form large molecules whose molecular weight is a multiple of that of the original substance. When two or more monomers are involved, the process is called copolymerization or heteropolymerization. See also *Degree of, Condensation,* and *Polymer.*

POLYMERIZE—To unite molecules of the same kind into another compound having the elements in the same proportion but possessing much higher molecular weight and different physical properties.

POLYMETHYL METHACRYLATE—A thermoplastic material composed of polymers of methyl methacrylate. It is a transparent solid with exceptional optical properties and good resistance to water. It is obtainable in the form of sheets, granules, solutions, and emulsions. It is extensively used for aircraft domes, lighting fixtures, decorative articles, etc.; it is also used in optical instruments and surgical appliances.

POLYSTYRENE—A water-white thermoplastic produced by the polymerization of styrene (vinyl benzene). The electrical insulating properties of polystyrene are outstandingly good and the material is relatively unaffected by moisture. In particular the power loss factor is extremely low over the frequency range 10^3-10^8 c.p.s.

POLYVINYL ACETATE—A thermoplastic material composed of polymers of vinyl acetate in the form of a colorless solid. It is obtainable in the form of granules, solutions, latices, and pastes, and is used extensively in adhesives, for paper and fabric coatings, and in bases for inks and lacquers.

POLYVINYL ALCOHOL—A thermoplastic material composed of polymers of the hypothetical vinyl alcohol. Usually a colorless solid, insoluble in most organic solvents and oils, but soluble in water when the content of hydroxy groups in the polymer is sufficiently high.

The product is normally granular. It is obtained by the partial hydrolysis or by the complete hydrolysis of polyvinyl esters, usually by the complete hydrolysis of polyvinyl acetate. It is mainly used for adhesives and coatings.

POLYVINYL BUTYRAL—A thermoplastic material derived from a polyvinyl ester in which some or all of the acid groups have been replaced by hydroxyl groups and some or all of these hydroxyl groups replaced by butyral groups by reaction with butyraldehyde. It is a colorless flexible tough solid.

It is used primarily in interlayers for laminated safety glass.

POLYVINYL CHLORIDE (P.V.C.)—A thermoplastic material composed of polymers of vinyl chloride; a colorless solid with outstanding resistance to water, alcohols, and concentrated acids and alkalies. It is obtainable in the form of granules, solutions, latices, and pastes. Compounded with plasticizers it yields a flexible material superior to rubber in aging properties. It is widely used for cable and wire coverings, in chemical plants, and in the manufacture of protective garments.

POLYVINYL CHLORIDE `ACETATE—A thermoplastic material composed of copolymers of vinyl chloride and vinyl acetate; a colorless solid with good resistance to water, and concentrated acids and alkalies.

It is obtainable in the form of granules, solutions, and emulsions. Compounded with plasticizers it yields a flexible material superior to rubber in aging properties. It is widely used for cable and wire coverings, in chemical plants, and in protective garments.

POLYVINYLIDENE CHLORIDE—A thermoplastic material composed of polymers of vinylidene chloride (1,1-dichloroethylene). It is a white powder with softening temperature at 185-200° C. The material is also supplied as a copolymer with acrylonitrile or vinyl chloride, giving products which range from the soft flexible type to the rigid type. Also known as saran.

POSITIVE MOLD—A mold designed to trap all the molding material when it closes.

POSTFORMING—The forming, bending, or shaping of fully cured, C-stage thermoset laminates that have been heated to make them flexible. On cooling, the formed laminate retains the contours and shape of the mold over which it has been formed.

POT LIFE—See *Working Life.*

POTTING—Similar to *Encapsulating* (q.v.), except that steps are taken to insure complete penetration of all the voids in the object before the resin polymerizes.

POWER FACTOR—In an insulating material, the ratio of total power loss (watts) in the material to the product of voltage and current in a capacitor in which that material is a dielectric.

PRECIPITATE (*n.*) — Material which is separated out of a solution in the form of a solid. (*v.*)—Act of separating out such solid by physical or chemical means.

PREFORM (*n.*)—A compressed tablet or biscuit of plastic composition used for efficiency in handling and accuracy in weighing materials. (*v.*)—To make plastic molding powder into pellets or tablets.

PREHEATING—The heating of a compound prior to molding or casting in order to facilitate the operation or to reduce the molding cycle.

PREIMPREGNATION—In reinforced plastics molding, it is used to refer to applying the resin to the reinforcing material before shipping it to the molder who will use it.

PREMIX—In reinforced plastic molding, the material made by "do-it-yourselfers," molders, or end-users who purchase polyester resin, reinforcement, fillers, etc., separately and mix the reinforced molding compounds on their own premises.

PREPLASTICATION—Technique of premelting injection molding powders in a separate chamber, then transferring the melt to the injection cylinder. Device used for preplastication is commonly known as a preplasticizer. See *Plasticate.*

PREPLASTICIZE (Preplasticizer)—See *Preplastication*

PREPREG—A term generally used in reinforced plastics to mean the reinforcing material containing or combined with the full complement of resin before molding.

PREPRINTING—In sheet thermoforming, the distorted printing of sheets before they are formed. During forming the print assumes its proper proportions.

PRESS POLISH—A finish for sheet stock produced by contact, under heat and pressure, with a very smooth metal which gives the plastic a high sheen.

PRESSURE PADS—Reinforcements of hardened steel distributed around the dead areas in the faces of a mold to help the land absorb the final pressure of closing without collapsing.

PRESSURE-SENSITIVE ADHESIVE—An adhesive made so as to adhere to a surface at room temperature by briefly applied pressure alone.

PULL-BACK—Device to bring the press platen to the open position by the operation of hydraulic cylinders; also used to operate ejection devices. See *Push-back.*

PULP—A fibrous cellulosic mass into which wood or vegetable products may be converted by prolonged cooking to remove non-cellulosic matter.

PULP MOLDING—Process by which a resin-impregnated pulp material is preformed by application of a vacuum and subsequently oven cured or molded.

PURGING—Cleaning one color or type of material from the cylinder of an injection molding machine by forcing it out with the new color or material to be used in subsequent production. Purging materials are also available.

PUSH-BACK—A device (usually hydraulic) used to open the press and supply the force to eject the molded parts.

R

RADIO FREQUENCY—A frequency within the range used for radio communication and radio frequency heating. In radio frequency preheating the frequencies most commonly used are between 10 and 100 megacycles.

RAM—See *Force Plug.*

RAM TRAVEL—The distance the injection ram moves in filling the mold, in either injection or transfer molding.

REINFORCED MOLDING COMPOUND—Compound supplied by raw material producer in the form of ready-to-use materials; as distinguished from premix (q.v.).

REINFORCEMENT—a strong inert material bound into a plastic to improve its strength, stiffness, and impact resistance. Reinforcements are usually long fibers of glass, sisal, cotton, etc.—in woven or non-woven form. To be effective, the reinforcing material must form a strong adhesive bond with the resin.

RELATIVE HUMIDITY—Ratio of the quantity of water vapor present in the air to the quantity which would saturate it at any given temperature.

RELATIVE VISCOSITY—The relative viscosity of a polymer in solution is the ratio of the absolute viscosities of the solution (of stated concentration) and of the pure solvent at the same temperature.

$$\eta_r = \frac{\eta}{\eta_0}$$

where η_r = relative viscosity, η = absolute viscosity of polymer solution, η_0 = absolute viscosity of pure solvent.

RELEASE AGENT—See *Parting Agent.*

RESIN—Any of a class of solid or semi-solid organic products of natural or synthetic origin, generally of high molecular weight with no definite melting point. Resins are generally water-insoluble and have little or no tendency to crystallize. However, certain resins, such as some polyvinyl alcohols and polyacrylates, are readily dispersible in water, and others, such as polyamides and polyvinylidene chloride, are readily crystallized. See also *Gum.*

RESINOID—Any of the class of thermosetting synthetic resins, either in their initial temporarily fusible state or in their final infusible state. Compare with *Thermosetting.*

RESIN POCKET—An apparent accumulation of excess resin in a small, localized section visible on cut edges of molded surfaces.

RESISTIVITY—The ability of a material to resist passage of electrical current either through its bulk or on a surface. The unit of volume resistivity is the ohm-cm., of surface resistivity, the ohm.

RESTRICTED GATE—A thin gate which, with some materials, helps to prevent residual molding stresses and so lowers the tendency of the part to stick in the mold and craze afterward.

RETAINER PLATE—The plate on which demountable pieces, such as mold cavities, ejector pins, guide pins, and bushings are mounted during molding; usually drilled for steam or water.

RETARDER—See *Inhibitor.*

RIB—A reinforcing member of a fabricated or molded part.

RIGID P.V.C.—Polyvinyl chloride or a polyvinyl chloride/acetate copolymer characterized by a relatively high degree of hardness; it may be formulated with or without a small percentage of plasticizer.

RIGID RESIN—One having a modulus high enough to be of practical importance, e.g., 10,000 p.s.i. or greater.

ROOM TEMPERATURE SETTING ADHESIVES—Adhesives which set at 68 to 86° F., inclusive, the limits for room temperature that are specified in ASTM D 618.

ROSIN—A resin obtained as a residue in the distillation of crude turpentine from the sap of the pine tree (gum rosin) or from an extract of the stumps and other parts of the tree (wood rosin).

ROTATIONAL CASTING—A hollow sectional mold is charged with a measured amount of fluid plastisol and rotated. The plastisol is forced against the interior surface of the mold by centrifugal force and, as the temperature of the material rises, it forms a gelled film on that surface. Heating of the mold is continued until the gelled plastisol reaches the fusion temperature, after which it is cooled and the molding is stripped from the mold.

ROVING—Fibrous glass reinforcement made from "cake" packages. A number of continuous strands are wound on a tube to form a cylindrical package; the number of strands can be varied—usually 60 "end" rovings are made.

RUNNER—In an injection mold, the groove that connects the sprue with the gate through which the plastic composition flows.

S

SANDWICH CONSTRUCTIONS—Panels composed of a lightweight core material—honeycomb, foamed

plastic, etc., q.v.—to which two relatively thin, dense, high strength faces or skins are adhered.

SATURATED COMPOUNDS—Organic compounds which do not contain double or triple bonds and thus cannot add on elements or compounds.

SCORING—Scratching of the surface of a mold caused by interference due to mis-matching or oversized force plug.

SCRAP—Sprues, runners, rejects, and other thermoplastic waste material which can be reground to particle size and mixed with virgin material for re-use.

SEGREGATION—A close succession of parallel, relatively narrow and sharply defined, wavy lines of color on the surface of a plastic which differ in shade from surrounding areas, and create the impression that the components have separated.

SEMI-AUTOMATIC PRESS—A hydraulic press in which certain operations are automatic.

SEMI-POSITIVE MOLD—A mold which allows a small amount of excess material to escape when it it closed. See *Flash Mold, Positive Mold.*

SET (*v.*)—To convert a liquid resin or adhesive into a fixed or hardened state by chemical or physical action, such as condensation, polymerization, oxidation, vulcanization, gelation, hydration, or evaporation of volatile constituents. See also *Cure.*

SETTING TEMPERATURE—The temperature to which a liquid resin, an adhesive, or products or assemblies involving either is subjected to set the resin or adhesive.

SETTING TIME—The period of time during which a molded or extruded product, an assembly, etc., is subjected to heat and/or pressure to set the resin or adhesive.

SHEAR STRENGTH—a) The ability of a material to withstand shear stress. b) The stress at which a material fails in shear.

SHEETER LINES—Parallel scratches or projecting ridges distributed over a considerable area of a plastic sheet.

SHELF LIFE—See *Storage Life.*

SHORT—Mark on surface of a molded article indicating incomplete filling of the mold.

SHOT—The yield from one complete molding cycle.

SHOT CAPACITY—The maximum weight of material which an injection machine can inject per cycle into a mold.

SHRINK FIXTURE—See *Cooling Fixture.*

SIDE BARS—Loose pieces used to carry one or more molding pins, and operated from outside the mold.

SIDE DRAW PINS—Projections used to core a hole in a direction other than the line of closing of a mold, and which must be withdrawn before the part is ejected from the mold.

SILICONE—One of the family of polymeric materials in which the recurring chemical group contains silicon and oxygen atoms as links in the main chain. At present these compounds are derived from silica (sand) and methyl chloride. The various forms obtainable are characterized by their resistance to heat.

Silicones are used in the following applications: *a*) Greases for lubrication. *b*) Rubber-like sheeting for gaskets, etc. *c*) Heat-stable fluids and compounds for waterproofing, insulating, etc. *d*) Thermosetting insulating varnishes and resins for both coating and laminating.

SINK-MARK—Dimple-like depression in the surface of a molded piece indicating that it has retracted from the mold; mark has well-rounded edges and shows a surface film.

SINKING A MOLD—See *Hobbing.*

SINTERING—In forming articles from fusible powders, e.g., nylon, the process of holding the pressed-powder article at a temperature just below its melting point for about ½ hour. Particles are fused (sintered) together, but the mass, as a whole, does not melt.

SIZING (*n.*)—The process of applying a material to a surface to fill pores and thus reduce the absorption of the subsequently applied adhesive or coating or to otherwise modify the surface. Also, the surface treatment applied to glass fibers used in reinforced plastics. The material used is sometimes called *Size.*

SLIP FORMING—Sheet forming technique in which some of the plastic sheet material is allowed to slip through the mechanically operated clamping rings during a stretch-forming operation.

SLIP-PLANE—Plane within transparent material visible in reflected light, due to poor welding and shrinkage on cooling.

SLURRY PREFORMING—Method of preparing reinforced plastics preforms by wet processing techniques similar to those used in the pulp molding (q.v.) industry.

SLUSH MOLDING—Method for casting thermoplastics, in which the resin in liquid form is poured into a hot mold where a viscous skin forms. The excess slush is drained off, the mold is cooled, and the molding stripped out.

SNAP-BACK FORMING—Sheet forming technique in which an extended heated plastic sheet is allowed to contract over a male form shaped to the desired contours.

SOLUTION—Homogeneous mixture of two or more components, such as a gas dissolved in a gas or liquid, or a solid in a liquid.

SOLVENT—Any substance, usually a liquid, which dissolves other substances.

SOLVENT MOLDING—Process for forming thermoplastic articles by dipping a male mold in a solution or dispersion of the resin and drawing off the solvent to leave a layer of plastic film adhering to the mold.

SPECIFIC ADHESION—Adhesion between two surfaces which are held together by valence forces of the same type as those which give rise to cohesion. See also *Mechanical Adhesion.*

SPECIFIC GRAVITY—The ratio of the weight of the molded piece as compared to the weight of an equal volume of water.

SPECIFIC VISCOSITY—The specific viscosity of a polymer is the relative viscosity of a solution of known concentration of the polymer minus one. It is usually determined for a low concentration of the polymer (0.5 g. per 100 ml. of solution or less).

$$\eta_{SP} = \frac{\eta - \eta_o}{\eta_o} = \eta_r - 1,$$

where η_{SP} = specific viscosity η_r = relative viscosity.

SPINNERET—A metal plate with holes through which a plastic material passes into a solidifying medium, to form filaments or fibers.

SPINNING—Process for producing

synthetic fibers and filaments by forcing a viscous resin solution through fine holes in a *spinneret*, q.v.

SPIN WELDING—A process of fusing two objects together by forcing them together while one of the pair is spinning, until frictional heat melts the interface. Spinning is then stopped and pressure held until they are frozen together.

SPLIT-RING MOLD—A mold in which a split cavity block is assembled in a chase to permit the forming of undercuts in a molded piece. These parts are ejected from the mold and then separated from the piece.

SPRAYED METAL MOLDS—Mold made by spraying molten metal onto a master until a shell of predetermined thickness is achieved. Shell is then removed and backed up with plaster, cement, casting resin, or other suitable material. Used primarily as a mold in sheet-forming processes.

SPREAD—The quantity of adhesive per unit joint area applied to an adherend. It is preferably expressed in pounds of liquid or solid adhesive per thousand square feet of joint area. *Single spread* refers to application of adhesive to only one adherend of a joint. *Double spread* refers to application of adhesive to both adherends.

SPREADER—A streamlined metal block placed in the path of flow of the plastics material in the heating cylinder of extruders and injection molding machines to spread it into thin layers, thus forcing it into intimate contact with the heating areas.

SPRUE—Feed opening provided in the injection or transfer mold; also the slug formed at this hole. *Spur* is a shop term for the sprue slug.

SPRUE BUSHING—A hardened steel insert in an injection mold which contains the tapered sprue hole and has a suitable seat for the nozzle of the injection cylinder. Sometimes called an *Adapter*.

SPRUE LOCK—In injection molding, a portion of the plastic composition which is held in the cold slug well by an undercut; used to pull the sprue out of the bushing as the mold is opened. The sprue lock itself is pushed out of the mold by an ejector pin. When the undercut occurs on the cavity block retainer plate, this pin is called the *Sprue Ejector Pin*.

STABILIZER—An ingredient used in the formulation of some plastics, especially elastomers, to assist in maintaining the physical and chemical properties of the compounded materials at their initial values throughout the processing and service life of the material.

STAPLE FIBERS—Fibers of spinnable length manufactured directly or by cutting continuous filaments to short lengths.

STARVED JOINT—A joint which has an insufficient amount of adhesive to produce a satisfactory bond.

STEAM PLATE—Mounting plate for molds, cored for circulation of steam.

STEROSPECIFIC—Loosely defined as "the arrangement of molecules in a specified form." More specifically, it is described as the arrangement of polymers in a predetermined geometric form rather than in random fashion.

STITCHING—The progressive welding of thermoplastic materials by successive applications of two small mechanically operated electrodes, connected to the output terminals of a radio frequency generator, using a mechanism similar to that of a normal sewing machine.

STORAGE LIFE—The period of time during which a liquid resin or packaged adhesive can be stored under specified temperature conditions and remain suitable for use. Storage life is sometimes called *Shelf Life*.

STRETCH FORMING—A plastic sheet forming technique in which the heated thermoplastic sheet is stretched over a mold subsequently cooled.

STRIPPER-PLATE—A plate that strips a molded piece from core pins or force plugs. The stripper-plate is set into operation by the opening of the mold.

SUBSTRATE—A material upon the surface of which an adhesive containing substance is spread for any purpose, such as bonding or coating. A broader term than *Adherend*.

SURFACE RESISTIVITY—The electrical resistance between opposite edges of a unit square of insulating material. It is commonly expressed in ohms. (Also covered in ASTM D257-54T.)

SUSPENSION—Dispersion of a solid in a liquid.

SWEATING—Exudation of small drops of liquid, usually a plasticizer or softener, on the surface of a plastic part.

SYNTHETIC (*n.*, *a.*)—Chemical compound made from elements or simple compounds; applied particularly to substances that duplicate other substances occurring in nature.

SYNTHETIC RESIN—A complex, substantially amorphous, organic semi-solid, or solid material (usually a mixture) built up by chemical reaction of comparatively simple compounds, approximating the natural resins in luster, fracture, comparative brittleness, insolubility in water, fusibility or plasticity, and some degree of rubber-like extensibility; but commonly deviating widely from natural resins in chemical constitution and behavior with reagents.

T

TACK—Stickiness of an adhesive, measurable as the force required to separate an adherend from it by viscous or plastic flow of the adhesive.

TACK RANGE—The period of time in which an adhesive will remain in the tacky-dry condition after application to an adherend, under specified conditions of temperature and humidity.

TAPPING—Cutting threads in the walls of a circular hole.

TAR—Dark-colored substance of variable composition, liquid or semi-liquid at room temperature, often possessing a characteristic odor, usually insoluble in water but soluble in carbon disulfide, benzol, etc., and which on distillation, oxidation, etc., forms a pitch.

TENSILE STRENGTH—The pulling force necessary to break a given specimen, divided by the cross-sectional area.

THERMAL CONDUCTIVITY—Ability of a material to conduct heat; physical constant for quantity of heat that passes through unit volume of a substance in unit of time when difference in temperature of two faces is 1°.

THERMAL EXPANSION—See *Coefficient of*.

THERMOPLASTIC (*a.*)—Capable of being repeatedly softened by heat and hardened by cooling. (*n.*)—A material that will repeatedly soften

when heated and harden when cooled.

THERMOSET—A material that will undergo or has undergone a chemical reaction by the action of heat, catalysts, ultra-violet light, etc., leading to a relatively infusible state.

THERMOSETTING RESIN—A synthetic resin which will harden and become permanently infusible and insoluble under the influence of heat.

THIXOTROPY—The property by which some compositions become solid at rest but liquefy again on agitation.

THREAD PLUG—A part of a mold that shapes an internal thread and must be unscrewed from the finished piece.

TOGGLE ACTION—A mechanism which exerts pressure developed by the application of force on a knee joint. It is used as a method of closing presses and also serves to apply pressure at the same time.

TOLERANCE—The maximum variation in accuracy in the size of a molded or fabricated piece to be satisfactory for assembly.

TORPEDO—The torpedo-shaped device fitted into the center of the heating chamber of an injection machine to assist in the transfer of heat to the material.

TRANSFER MOLDING—A method of molding thermosetting materials, in which the plastic is first softened by heat and pressure in a transfer chamber, then transferred through suitable sprues, runners, and gates into a closed mold for final curing.

TUMBLING—Finishing operation for small plastic articles by which gates, flash, and fins are removed and/or surfaces are polished by rotating them in a barrel together with wooden pegs, sawdust, and polishing compounds.

U

ULTRA-VIOLET—Zone of invisible radiations beyond the violet end of the spectrum of visible radiations. Waves are shorter than those of light and characterized by chemical action.

UNDERCUT—Any indentation in or protrusion from a molded piece beyond the direct draw line.

UNICELLULAR—With foamed plastics, each cell an isolated unit. Equals "closed-cell."

UNSATURATED COMPOUNDS—Compounds having more than one bond between two adjacent atoms and capable of adding other atoms at that point to reduce it to a single bond.

UREA FORMALDEHYDE RESIN (Urea Resin)—A synthetic resin derived from the reaction of urea (carbamide) with formaldehyde or its polymers.

V

VACUUM FORMING—Method of sheet forming in which the plastic sheet is clamped in a stationary frame, heated, and drawn down by a vacuum into a mold. In a loose sense, it is sometimes used to refer to all sheet forming techniques, including *Drape Forming* (q.v.), involving the use of vacuum and stationary molds.

VACUUM METALIZING—Depositing a metal coating on a plastic in a vacuum chamber.

VALUE—That attribute which describes the lightness of a color, e.g., a color may be classed as equivalent to some member of the series of grays ranging from black (the zero member) to white.

VENEER—A thin sheet of wood, generally within the thickness range of 0.01 to 0.0125 inch.

VENT—In a mold, a shallow channel or minute hole cut in the cavity to allow air to escape as the material enters.

VERTICAL FLASH RING—The clearance between the force plug and the vertical wall of the cavity in a positive or semi-positive mold; also the ring of excess material which escapes from the cavity into this clearance space.

VINYL RESIN—A synthetic resin formed by the polymerization of chemical compounds containing the group $CH_2 = CH-$.

VISCOSITY—Internal friction or resistance to flow of a liquid. The constant ratio of shearing stress to rate of shear.

VOLUME RESISTIVITY (Specific Insulation Resistance)—The electrical resistance between opposite faces of a 1-cm. cube of insulating material. It is measured under prescribed conditions using a direct current potential after a specified time of electrification. It is commonly expressed in ohm-centimeters. The recommended test is ASTM D257-54T.

VULCANIZATION—A chemical reaction in which the physical properties of a rubber are changed in the direction of decreased plastic flow, less surface tackiness, and increased tensile strength by reacting it with sulfur or other suitable agents.

W

WARM SETTING ADHESIVES—A term which is sometimes used as synonymous with Intermediate Temperature Setting Adhesives.

WARP—Dimensional distortion in a plastic object after molding.

WELD-MARK—Mark formed by the incomplete union of two or more streams of plastic material flowing together in a mold.

WELDING—1) Hot gas welding: A method of welding thermoplastic materials in which the material is heated by a jet of hot air or inert gas directed from a welding "torch" on to the area of contact of the surfaces which are being welded. Welding operations to which this method is applied normally require the use of a filler rod. 2) Especially in Europe, to mean heat sealing, either conductive or electronic.

WET STRENGTH—The strength of paper when saturated with water, especially used in discussions of processes whereby the strength of paper is increased by the addition, in manufacture, of plastics resins. Also, the strength of an adhesive joint determined immediately after removal from a liquid in which it has been immersed under specified conditions of time, temperature, and pressure.

WORKING LIFE—The period of time during which a liquid resin or adhesive, after mixing with catalyst, solvent, or other compounding ingredients, remains usable.

Y

YIELD VALUE—The lowest pressure at which a plastic will flow. Below this pressure the plastic behaves as an elastic solid; above, as a viscous liquid.

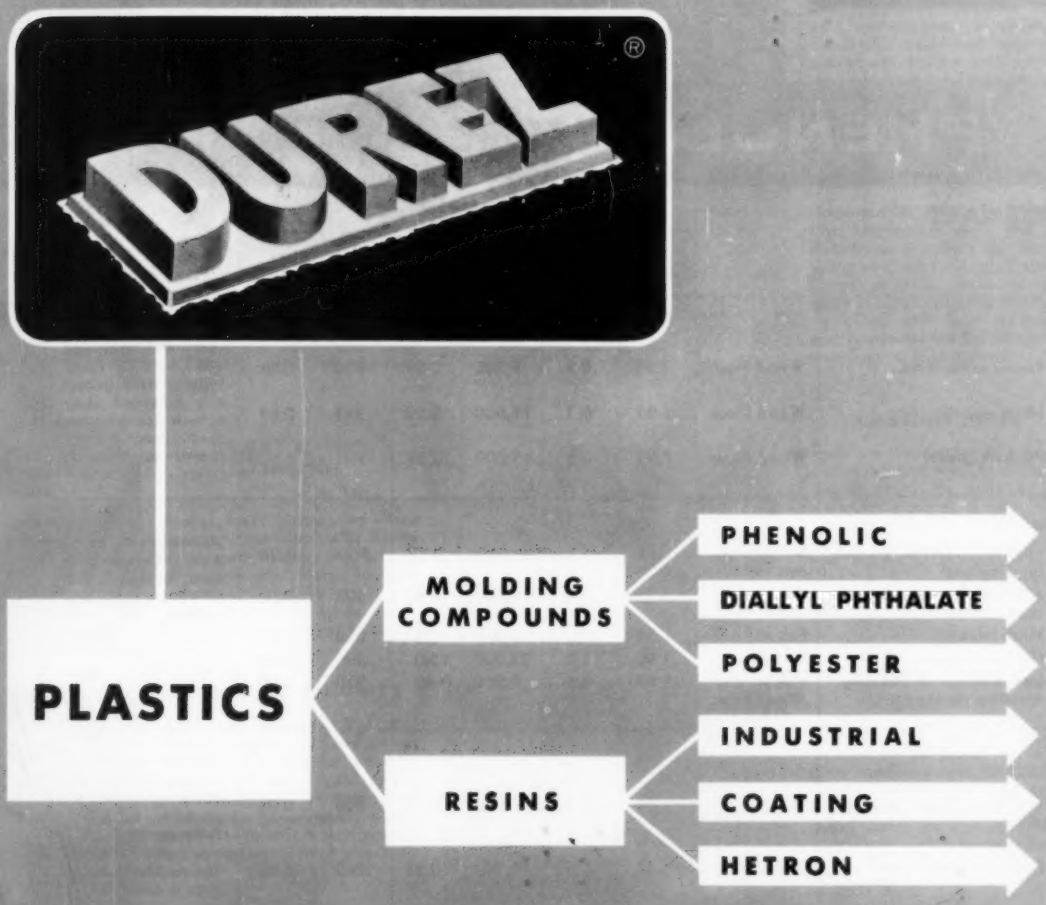
chem-o-sol® *gives you unlimited potential thru*

The World's Most Advanced Research

The World's Most Experienced Formulator

The World's Only Application Methods Plant

The World's Largest Production Capacity



chem-o-sol® *is Super Plastisol . . .*

Chem-o-sol is our trade name for specially formulated polyvinyl dispersions (plastisols), which free the designer from the limitations of conventional materials. Inherently versatile because of their "liquid solid" nature, these dispersions offer unlimited opportunity to solve old problems and to develop new products, new forms, new characteristics. They are simple to apply, whether adapted as coatings and finishes or as shaped components.

To give you the ultimate in this new production tool, we operate the world's largest plant — with the most modern facilities for research, application method development, and production of specialized formulations.

Call on these facilities to improve your present production, create new products, open entirely new fields.

Chemical Products
CORPORATION
KING PHILIP ROAD • EAST PROVIDENCE, R. I.
Member Vinyl Dispersions Division of The S.P.I.

A primary evaluation of the properties of the Durez plastics, and the combinations in which they are available in molding materials and resins, can be obtained from the data on the following pages.

The variety of these modern materials and their consistent uniformity reflect the experience of 35 years in developing, producing, and applying plastics to the needs of industry.

Engineers and designers seeking further information on materials combining the characteristics they require are invited to call on this experience. It is available through qualified technical men who can often assist in solving design, structural, and production problems.

PLASTICS *that fit the job*

HOOKER ®
CHEMICALS
PLASTICS

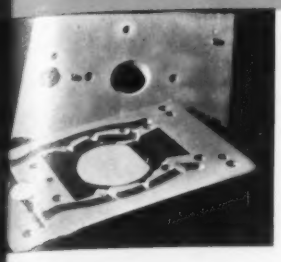
DUREZ® PLASTICS

Durez thermosetting phenolics offer mechanical, electrical, thermal, and chemical properties in hundreds of combinations. Each fulfills, within its intended field of application, a given set of requirements. Compression, transfer, or plunger presses can be used. An economy factor is that many of the molding compounds can be molded on automatic equipment.

The industrial resins exhibit similar properties, and frequently improve the characteristics of other materials when used as bonding and impregnating media. Durez coating resins are oil soluble and have wide use in applications such as wax emulsions, brushing and spraying finishes, varnishes and enamels.

PHENOLIC Molding Compounds

MATERIALS		Filler	PROPERTIES: Specific Gravity	Water Absorption	Flexural PSI	Impact FP inch notch	°F Diel. Strength V/m-s/t	Power Factor 1000 KC	USES
GENERAL-PURPOSE									Cases, housings, cabinets, and large and small parts of many types where generally balanced characteristics are desired. These are the lowest cost phenolic materials.
265	Fastest production.	Wood Flour	1.38	0.5	9,000	0.27	350	0.04	
791	Most versatile.	Wood Flour	1.37	0.7	11,000	0.28	325	0.03	
11540	Highest quality.	Wood Flour	1.37	0.6	11,000	0.31	350	0.035	
IMPACT									Automotive pump gears, telephone parts, bushings, caster wheels, tool parts, pulleys, and other applications subject to rough handling or heavy wear in service.
1544	Highest impact in granular type material.	Wood Flour and Flock	1.37	0.7	11,000	0.37	350	0.04	
1900	Medium impact nodular type material.	Fabric	1.42	1.2	10,000	0.6	300	0.06	
14482	High impact.	Fabric	1.38	1.0	10,000	1.8	350	0.04	
16221	Highest impact.	Fiberglas®	1.90	1.0	22,000	17.0	350	0.02	
16840	Low modulus of elasticity —resilient.	Rubber and Wood Flour	1.29	1.6	8,200	0.45	375	0.09	
NON-BLEEDING									Closures for medicinal, cosmetic and other packaged products, especially those containing liquids with alcohol. The molded appearance is excellent.
3949	General-purpose, minimum odor.	Wood Flour	1.38	0.8	9,000	0.28	200	0.05	
3971	Fast cure, good finish.	Wood Flour	1.38	0.5	9,000	0.28	260	0.05	
ELECTRICAL									Automotive, radio, TV transformer, X-ray, switch, appliance, and other electrical equipment parts requiring excellent dielectric and low-loss values.
2271	High dielectric strength at elevated temperatures.	Wood Flour	1.37	0.7	10,000	0.28	350	0.03	
16090	Good arc resistance.	Mineral	1.67	0.4	8,500	0.36	400	0.05	
16274	Low dissipation factor, high volume resistivity.	Mineral	1.75	0.06	9,500	0.30	375	0.013	
HEAT-RESISTANT									Electric iron and cooking utensil handles, toaster and coffee-maker parts, and other applications where high heat resistance is needed for durability and safety.
55	Good impact strength with excellent heat resistance.	Mineral and Flock	1.61	0.5	8,500	0.36	300	0.14	
1308	Most versatile.	Mineral and Wood Floor	1.57	0.4	9,500	0.26	350	0.05	
14893	Highest resistance.	Mineral	1.54	0.2	8,000	0.25	275	0.12	
SPECIAL PROPERTY									Washing machine components, textile machinery parts, chemical-resistant moldings, pump impellers and similar parts, and other applications requiring unusual combinations of properties.
75	Maximum resistance to acids, mild alkalies.		1.38	0.4	8,000	0.20	230	0.045	
13856	Good impact, excellent resistance to water.	Flock	1.41	1.0	9,500	0.48	200	0.05	
14900	Good impact, dimensional stability, gloss, water resistance.	Flock	1.38	0.4	9,000	0.32	250	0.05	
15328	Non-corrosive, general purpose.	Flock and Wood Flour	1.38	0.7	9,000	0.28	325	0.04	

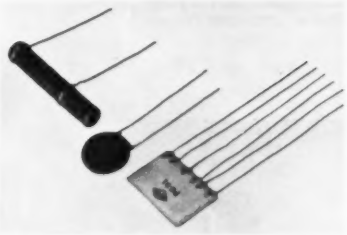


For information on Flame-Resistant Resins see data on HETRON®

PHENOLIC Industrial Resins

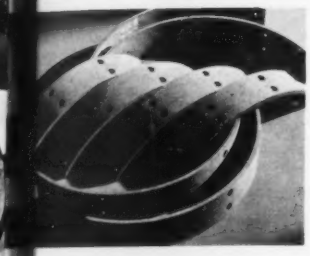
SHELL MOLDS FOR METAL CASTINGS

Improved phenolic foundry resins, including new types for coated sand, bring new efficiency and economy to the shell molding process. These resins produce shell molds and cores marked by exceptionally high strength, minimum curing cycles, and excellent pattern detail.



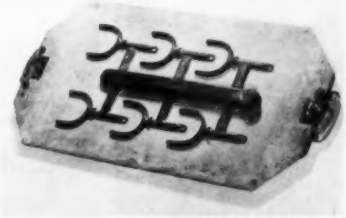
IN RUBBER COMPOUNDS

Durez resins are used in compounding stocks for shoe soles and heels, tool handles, and other moldings. Hardness, stiffness, and resistance to abrasion, chemicals, and heat are improved. Neoprene and acrylonitrile solvent-type cements are strengthened by the addition of Durez resins.



WOOD PARTICLE BONDING

Sawdust, shavings, and cuttings formerly wasted are mixed with Durez resin to make structural sheets and molded toilet seats, shoe forms, and other products. Resin helps make board sheets dense, strong, free from warp, and highly resistant to deterioration.

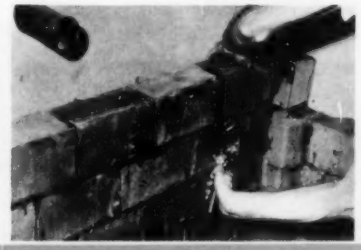


IN ELECTRICAL PARTS

Insulation for parts such as resistors, condensers, coils, and capacitors is provided by dense, strong coatings formulated with a Durez phenolic resin. In this material electrical properties are combined with heat insulation and freedom from the effects of exposure to high humidity.

BRAKE LINING BONDING

Automotive and aircraft brake linings, brake blocks, and clutch facings formulated with Durez resins wear longer. Stopping is easier and safer. Resins increase resistance to heat, water, oil, and grease. In lining-to-shoe bonds they eliminate the need for rivets.

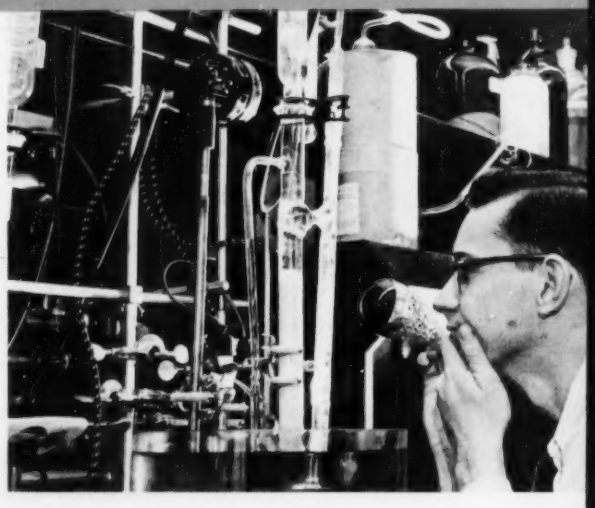


CASTING RESIN

Parts can be produced quickly and at low cost with Durez liquid casting resin. The resin is cast without the use of pressure, sets fast, requires only a mild bake, and is advantageous for short-run, model or prototype work, masking fixtures, novelty casting, foundry patterns, and special parts.

ABRASIVE BONDING

High heat resistance is an important property in Durez resins used to bind abrasive grains in grinding wheels, abrasive paper, and abrasive discs. Durez-bonded wheels can be run safely at unusually high speeds and operating temperatures, and give long service.



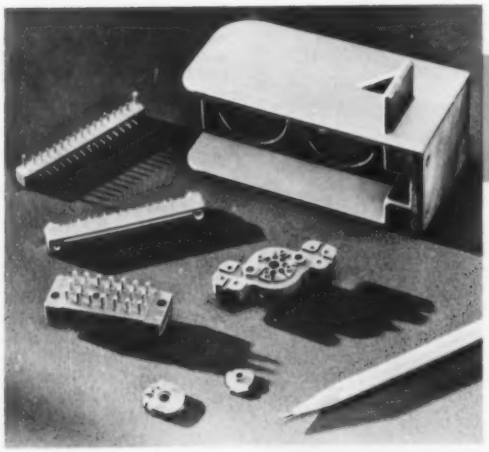
IN ACID-PROOF CEMENTS

Pickling tanks, fume stacks, absorption towers, floors, and other units lined with acid-proof brick require an equally acid-resistant cement. Durez furfuryl-alcohol resins in mortars enable such equipment to be used interchangeably in contact with acid or alkalies.

PHENOLIC Coating Resins

in WAX EMULSIONS, VARNISHES, PRINTING INKS, etc.

Coatings and finishes of many types are improved by formulation with Durez phenolic resins. The resins produce wax emulsions having excellent qualities of water resistance, wearability, slip resistance, and gloss retention. Resins for varnishes and enamels are soluble or readily dispersible in drying oils and improve the properties of brushing and spraying finishes with acid-, alkali-, and water-resistance, and durability. Durez resins are also useful in heat-set and gel-type printing inks.



For information on Flame-Resistant Resins see data on HETRON®

COLORED POLYESTER
Molding Compounds

New horizons in product design were opened up with the development of Durez thermosetting polyester molding compounds in a full range of opaque colors. These materials possess exceptionally high dimensional stability when molded, and their excellent electrical properties include high arc resistance. Recommended for business machine parts, radio and TV cabinets, shaver housings, telephone handsets, appliance and utensil handles, and other applications requiring versatile engineering properties plus color. Available in three grades: general-purpose, general-purpose self-extinguishing, and improved impact. Can be molded on automatic presses.

DIALLYL PHTHALATE
Molding Compounds

These thermosetting molding materials are giving highly dependable service in electrical applications where exposure to high humidity for long periods is encountered. They do not corrode metal inserts. They have excellent dimensional stability. Very fine electrical properties, low water absorption, and high impact strength are notable among the characteristics shown in the table below:

MATERIAL		PROPERTIES						
	Filler	Specific Gravity	Water Absorption	Flexural PSI	Impact FP inch-notch	Heat resist °F.	Diel. Strength V/m-s/t	Power Factor 1000 KC
16694	Orlon	1.31	0.2	10,500	0.55	240	400	0.02
17877	Mineral	1.65	0.2	8,500	0.3	300	390	0.08

FURTHER INFORMATION

We will gladly supply information about any of these molding compounds, industrial resins, and coating resins if you will tell us your specific interests. Much helpful information and data are available in published literature. Write us for whatever you need.

See what you can make with

Plastic-Light Metal-Tough Corrosion-Resistant Spencer Nylon

Many new profit opportunities are now waiting for you because of new Spencer Nylon's special advantages:

INJECTION MOLDING: Dozens of new profit opportunities are now open to manufacturers, because of new Spencer Nylon. For example, with Spencer Nylon it is now possible to injection-mold pieces that have large surface areas and thick cross sections. These pieces are amazingly light, yet durable as metal, and far more corrosion-resistant. New Spencer Nylon brings into range such multi-million pound uses as cases for portable radios, motor boat propellers, conveyor belt links and electric motor housings.

A problem with ordinary nylon has long been that it has a water-like viscosity at processing temperatures. And because it solidifies so quickly, molding large objects has been exceedingly difficult.

This problem is solved with new Spencer Nylon. Spencer Nylon has a wider plasticizing range, making it easier to handle and less likely to produce voids during molding. And because it has a wider temperature working range, it is less likely to degrade during processing.

EXTRUSION: Bigger nylon pipe, in diameters up to 6 inches, is possible with new Spencer Nylon, too—again because of superior processing qualities. Pipe made with new Spencer Nylon is unaffected by powerful chemicals, fats, oils and greases. (And because of Spencer Nylon's unusual properties, it is also ideally suited for coating wire and cable, for producing tubing and for extruding profiles.)

FILM: Spencer Nylon, which is unaffected by most hydrocarbons, extends the applications of plastic packaging materials into such fields as film pouches for oils and fats.

OTHER TECHNIQUES: Processing methods such as extrusion molding and centrifugal casting are possible with Spencer Nylon. Also, it is possible to weld or join Spencer Nylon with an adhesive.

ECONOMICAL: It often costs less to use Spencer Nylon instead of metal and other plastics. Compared with metal, its low specific gravity permits the production of more parts per pound. Manufacturing cost is cut by molding to close tolerances, rather than machine finishing.

FULL RANGE OF RESINS: Spencer's resins are designed for a wide variety of processing techniques and applications. This large family of resins has the closest-controlled specifications of any nylon. That's because it is made by continuous polymerization.

DON'T MISS YOUR SHARE of the profits in nylon's future. We'll be glad to advise you on new fields and markets. Just write to Spencer Nylon, Spencer Chemical Company, Dwight Bldg., Kansas City 5, Missouri.

PVC RESINS

More formulations for
greater-than-ever versatility

EXCELLENT SURFACE FINISH • GOOD FLEXURAL STRENGTH • RESISTANCE TO SHATTERING AND CRACKING • HIGH IMPACT STRENGTH • HIGH HEAT DISTORTION • WIDE CHOICE OF GRANULATIONS • UNLIMITED COLOR RANGE

FOR VACUUM FORMING, EXTRUSION, CALENDERING, INJECTION MOLDING—Recognizing industry's need for up-to-date, improved molding materials, Dow consistently offers you the most complete line of polystyrenes in the industry. There are new general-purpose Styron materials with improved flow and extrusion properties. You also have a range of high-impact Styron formulations to provide better heat resistance properties, glossier surface, and better moldability, making many applications possible for the first time. Each of the specialized formulations has been proven a champion . . . in the laboratory, in fabricating, in use by consumers. For low moisture absorption characteristics, for parts demanding accurate dimensional stability, for superior fabrication properties—Styron is *the* polystyrene to satisfy your exact need. Check Dow and see!

STYRON® polystyrene

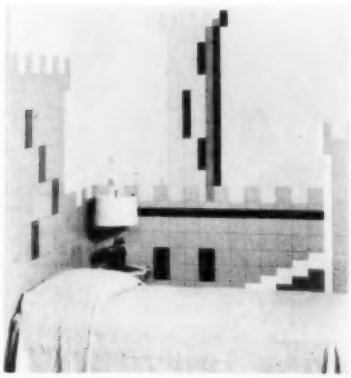
APPLICATIONS INCLUDE: RADIO CABINETS • APPLIANCE HOUSINGS • NUMEROUS INDUSTRIAL COMPONENTS • CUTLERY HANDLES • REFRIGERATOR COMPONENTS

APPLICATIONS INCLUDE: REFRIGERATION AND AUTOMOTIVE MATERIALS • BRISTLES • DENTURES • PENCIL BARRELS • DINNERWARE • AEROSOL

STYREX® a copolymer of styrene acrylonitrile

Excellent balance of physical properties

RIGID • CHEMICAL RESISTANT • GOOD HEAT RESISTANCE • HIGH CRITICAL ELONGATION • TOUGH • AVAILABLE WITH OR WITHOUT SURFACE LUBRICATION • IN NATURAL AND A WIDE RANGE OF TRANSPARENT AND OPAQUE COLORS • TAKES DECORATIVE COLORS AND FINISHES • EXCELLENT MOLDABILITY



FOR MOLDING AND EXTRUSION—With the introduction of Styrex in 1956, new horizons opened up for the plastics industry. Rigid and combining an excellent balance of physical properties, this new copolymer of styrene acrylonitrile is finding increased use in automotive materials and food containers, in numerous applications from tumblers to dentures. It provides high critical elongation and tensile strength with good heat resistance and improved toughness. It resists acids, bases, salts, oils, waxes, soaps, food stains, and many solvents including gasoline and kerosene. Styrex, with its ease of fabrication coupled with its excellent properties, provides a versatile molding material for many uses.

Refrigerator Inner Door Liner

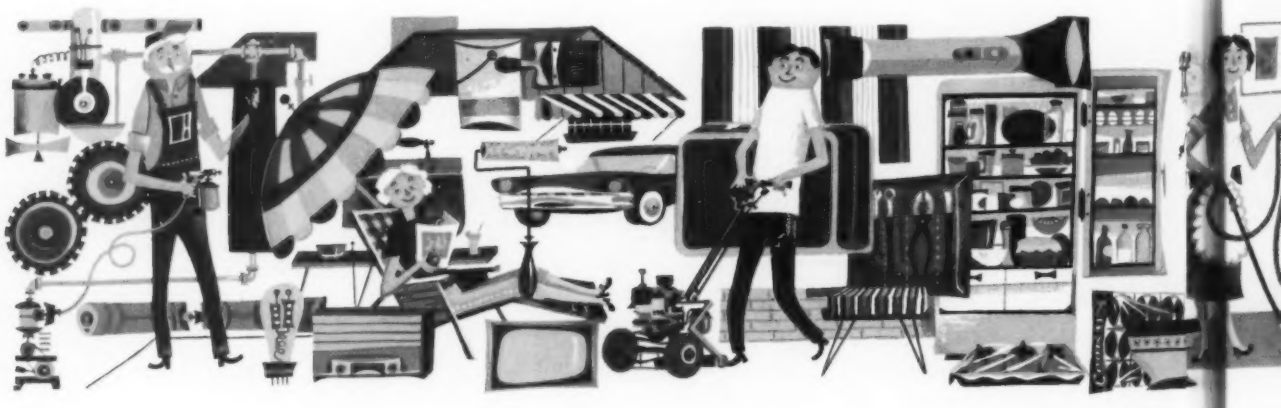
Cartridge Filter Housing

Unique resistance to chemicals and moisture



HIGH TENSILE STRENGTH • SELF-EXTINGUISHING • EXCELLENT CHEMICAL RESISTANCE • EASY TO CLEAN • EXCELLENT WEATHERING RESISTANCE • WILL NOT SUPPORT FUNGUS GROWTH • GOOD COLOR STABILITY

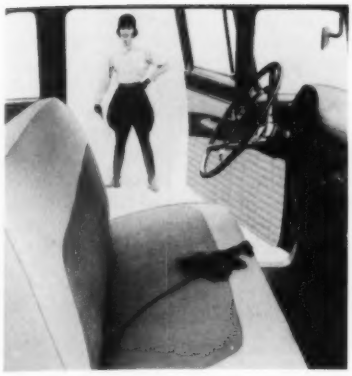
FOR TEXTILE FIBERS, EXTRUSION, INJECTION, COMPRESSION AND TRANSFER MOLDING, AND PACKAGING FILM—Because of an outstanding combination of properties, saran has become first choice among many users of plastics. In numerous cases, no other material meets service requirements as well as saran. It combines toughness, flexibility and durability with an amazing resistance to the abrasive and corrosive action of most chemicals. What's more, water absorption and vapor-transmission rate are extremely low. An outstanding food protector, an excellent lining for solution-carrying pipe, a superb fiber for outdoor fabrics—these only begin to indicate the unmatchable qualities of saran, one of the most inert of all thermoplastics. Let us tell you more.

SARAN

polymers and copolymers of vinylidene chloride plus similar materials

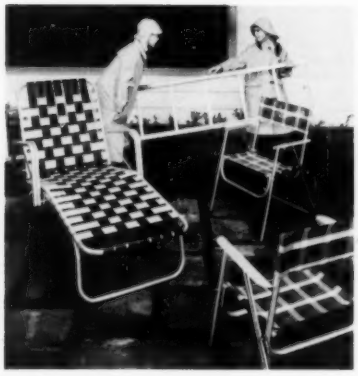
APPLICATIONS INCLUDE: PAINT GUN ATOMIZERS • RAYON SPINNER COUPLINGS • PIPE • FITTINGS • COUPLINGS • WINDOW SCREENING • AUTO SEAT COVERS AND UPHOLSTERY • AWNING

APPLICATIONS INCLUDE: ROLLER WHEELS FOR GARAGE DOORS • SELF-LUBRICATING GEARS • LUGGAGE END CAPS • LAWN MOWER ROLLERS • UNBREAKABLE FLASHLIG HOUSING



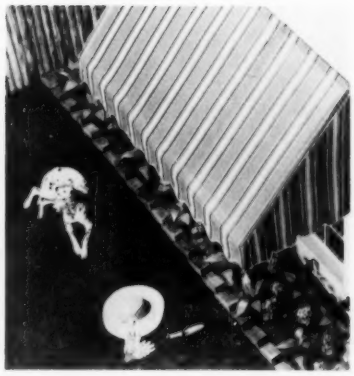
ETHOCEL®

an ethylcellulose molding compound



The aristocrat of thermoplastics

SELF LUBRICATING • LIGHT WEIGHT • RESISTANT TO MANY CHEMICALS • WITHSTANDS IMPACT OVER WIDE TEMPERATURE RANGE • LOW MOISTURE ABSORPTION • ODOR FREE • WIDE COLOR RANGE



FOR INJECTION MOLDING AND EXTRUSION—If you're looking for the very best, you've found it in Ethocel. Only Ethocel offers such characteristics as toughness, light weight, chemical and impact resistance over a wide temperature range. Takes extreme shocks with ease. Self lubricating compounds ideal for oilless gear and bearing applications. Free from odor, too. A variety of formulations answer your general purpose requirements and special assignments that call for great strength, excellent dimensional stability, shock resistance. Flexibility found in property combinations like this is reason enough for considering Ethocel, the aristocrat of thermoplastics!

FOR INJECTION MOLDING, EXTRUSION, PAPER COATING—From a broad background of experience in manufacturing ethylene chemicals and plastics has come Dow polyethylene. Its complete uniformity makes possible more profitable processing, fewer rejects and greater economy in quality output. With our versatile plant processes, property combinations can be varied almost to infinity. To supplement the well-known low density materials, Dow also produces the intermediate density type materials. In addition, linear or high density polyethylenes are being thoroughly researched and evaluated. This intriguing polyethylene family will definitely gain importance in shaping tomorrow's better products. For the very latest in uses and methods, for the right polyethylene today, give Dow a call now.

PVC RESINS polyvinyl chloride

For special and general-purpose requirements

VARIOUS GRANULATIONS • GREATER PLASTICIZER ABSORPTION • WIDER CHOICE OF PLASTICIZERS POSSIBLE • FREE FLOWING IN DRY BLEND PROCESSING • SHORTER BLENDING CYCLES • FASTER EXTRUSION RATES • HIGHEST UNIFORMITY • SUPERIOR CLEANLINESS

FOR EXTRUSION, WIRE COATING, CALENDERING, MOLDING—Dow PVC resins represent a dramatic advance to the trade, because they are versatile and easy to fabricate. General purpose and specialized requirements are met with four formulations in various granulations. Each of these compounds—PVC-100, PVC-111, PVC-133 and the newest addition, PVC-144—contributes to lower cost fabricating, more attractive products of greater durability and utility. Faster absorption of polymeric plasticizers and shorter blending cycles are only two of the profit-making advantages available to you. And improvements are forthcoming continually as Dow draws on resources and polymerization experience dating back to the infancy of the thermoplastics industry. Dow PVC resins—your answer for topping competition!

FROM EXPERIENCE AND YOUTH COME NEW IDEAS AND SOLUTIONS TO YOUR PLASTICS PROBLEMS

A pioneer in thermoplastics development, production and service, Dow today is a leader in this vital field. Technical service laboratories are maintained in Midland, Michigan; Freeport, Texas; Allyn's Point, Connecticut; and Torrance, California . . . where research scientists, technicians and engineers have helped shape the ever-expanding future for plastics.

Many of these dedicated men have grown with the industry from its beginning. (One Dow inventor holds more than 300 patents on plastics and related developments!) Their experience, plus the talents of production, styling, color and marketing service, combine to give you unequaled support in selecting, fabricating, forming and selling plastic products.

DOW®

Papers, technical bulletins and brochures covering every detail of plastics application, methods and equipment have been written and kept up to date. Any and all of this literature on Dow plastics is yours for the asking.

This service is backed by the industry's most complete facilities and is enhanced by a constant influx of new personnel. Each year, carefully selected college graduates join our plastics group, adding new vision, ideas and vitality.

To take advantage of our customer-service program—for more information on any member of America's First Family of Thermoplastics—contact us direct. Or write, wire or phone our nearest sales office.

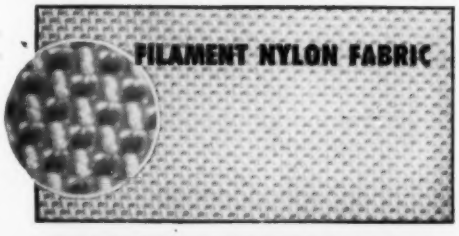
Wellington Sears fabrics insure superior performance for high and low pressure LAMINATING

IMPACT STRENGTH... Wellington Sears single filling duck has the right weight and rugged, hard-gripping texture to make an excellent reinforcement for C grade laminates where high impact strength is important, as in the case of certain gears, safety helmets and mechanical parts of many kinds. Available in widths of 29 inches and wider and in weights from about 8 to 15 ounces per square yard.



SHOCK RESISTANCE... Wellington Sears gear duck, like our Superior army duck, is a heavy, rugged fabric, ideal for shock-resistant laminates such as heavy duty mechanical parts in mechanisms subject to sudden starts and stops. Its plied yarn construction contributes high fiber density and freedom from sizing substances that sometimes hinder impregnation. Available in widths of 28½ inches and wider and in weights from about 8 to 15 ounces per square yard. Other Wellington Sears quality cotton fabrics for laminating include drills, Columbus sheeting, single and plied yarn chafers, and numerous special constructions.

GOOD INSULATOR... The nylon staple fibers in this fabric contribute high bonding strength and provide laminates with superior insulation resistance under high humidity conditions, a factor of special importance in items for the electronic and high frequency fields. Wellington Sears staple fiber nylon fabrics are made 28 to 72 inches wide in weights of about 4 ounces per square yard and higher. Also available to laminators are Wellington Sears fabrics of Orlon*, Dacron** and other synthetic fibers.

BALLISTIC PROPERTIES... In this fabric the strength of nylon yarns in filament form provides outstanding impact resistance to low pressure laminates such as wing board liners for military aircraft. Wellington Sears filament nylon fabrics are made in weights of about 2 ounces per square yard and higher, in widths from 28 to 72 inches. They are available in the grey or scoured and heat set for dimensional stability.

MULTI-DIRECTIONAL STRENGTH... Originally designed specifically for high pressure laminating, Lantuck is a non-woven, resin-bonded fabric whose revolutionary feature of random fiber distribution gives laminates equal strength in all directions and exceptional machineability at high cutting speeds. New, improved Lantuck is recommended as an economical filler for fine gears, bobbin heads and other laminates requiring sharp projections or edges, mirror-like machined surfaces and superior mechanical strength. Lantuck for laminating is 38 to 40 inches wide, weighing about 4 ounces per square yard, of various fibers and bonding agents.

*Reg. U.S. Pat. Off.

No matter what plastic or plastic-like material you work with, when you depend on Monsanto you can always choose a compatible plasticizer system . . . avoid incompatibility and undesirable plasticizer exudation. You get wide compounding latitude, too, when you work with Monsanto plasticizers. That's because of the many excellent combinations available for virtually every need.

Such convenient variety from one source is possible because Monsanto is America's most diversified supplier of plasticizers . . . originator of that industry standard, DOP . . . only source of chlorinated polyphenyls . . . producer of more than 50 different individual plasticizers in more than 7 basic chemical types. Nowhere else can you get such a choice selection of plasticizers for every practical purpose.

R—Recommended as satisfactory RC—Recommended in combination with other plasticizers

Monsanto Plasticizer Services

Monsanto has the plasticizers for you. But more than that, for your specific questions and compounding problems Monsanto maintains a Plasticizer Council Service for technical group guidance. To put this select team of technical people to work for you, ask your local Monsanto representative to help you fill out a "Plasticizer Council" request card. Quickly you'll receive qualified solutions to situations such as these and many others:

Calendered Vinyls

Need higher gloss in flooring? Monsanto Plasticizer Council recommend you try one of these three plasticizers—Santicizer 140, Santicizer 160 and Monsanto TCP—to improve gloss. Your floor tile will collect less dirt, clean easier, need less waxing to have more consumer appeal.

Other typical problems for which they can provide answers are how to

- *improve light stability of vinyl film*
- *impart flame resistance to sheeting*
- *lend film better hand*
- *give more permanent flexibility*

Vinyl Extrusions

Looking for nontoxic blown film formulations? Monsanto Plasticizer Council recommend Santicizer 141 as one ingredient. It not only meets BAI and FDA specifications but also speeds up blending, improves clarity and gloss through faster, more thorough solvating action.

Monsanto also has suggestions for

- *lowering compound costs*
- *resisting hydrolysis in electrical wire insulation*
- *obtaining faster, smoother dry blends*
- *achieving greater water resistance*

Vinyl Dispersions & Solutions

Want longer shelf life for plastisols? Monsanto Plasticizer Council recommend DIDA and DIDP as specialty plasticizers to retard thickening and prevent gelling at room temperatures. DIDA offers low-temperature flex properties as well.

Can we help you get

- *faster fusion in slush molding?*
- *diminished dilatancy for coating fabrics?*
- *increased abrasion resistance?*
- *better cell structure in foams?*

Other Plastics

Injection molding nylon? Monsanto Plasticizer Council suggest Santicizer 8 to extend polyamides, reduce raw-material costs. It also increases flexibility and toughness, and lowers the melting point to cut molding costs.

Perhaps your question is similar to one of these: "How can I get

- *higher dimensional stability in my acetate sheet?"*
- *lower cost in ethyl cellulose hot melts?"*
- *more uniform dispersion of fillers in phenolics?"*
- *special properties for my nitrocellulose coatings?"*

Whatever your problem in plasticizing, Monsanto will be happy to help you solve it, whether it concerns processing ease and speed, physical properties of the end product, or cost reductions. In addition to expert technical assistance and a wide selection of top-quality plasticizers for every need, you get one-stop service, mixed bulk shipment at bulk prices, and prompt delivery. If we may be of service to you in any way, just fill in the coupon or write.

Marblette Cast Phenolic Resins

Marblette is a pure, synthetic resin, unlike molding powders which are mixed with large amounts of fillers.

Marblette is sold in sheets, rods, tubes and special shapes in forms and colors designated below.

Jewel-like depth and complete color range enable Marblette to duplicate the appearance of such precious stones as amber, jade, coral, etc., as well as tortoise shell and ivory.

Marblette can be had in transparent, translucent and opaque forms in an infinite variety of plain colors and mottled effects.

Marblette can be supplied in water-clear form known as "Crystle" which is also made in a wide range of colors and shades.

PROPERTIES

Specific Gravity	1.30-1.32
Specific Volume, cubic inch per lb.	20-23
Tensile Strength, lbs. per sq. inch	8000-12000
Compressive Strength, lbs. per sq. inch	15000-30000
Impact Strength, ft. lbs. per inch of notch (Izod Test)	0.40-0.50
Modulus of Elasticity, lbs. per sq. inch x 10^5	4
Thermal Conductivity 10^4 cal., per second, per square cm/1° C. per cm	3-5
Thermal Expansion 10^5 per degree C.	8-11
Specific heat, cal. per degree C. per gram.	0.3-0.4
Heat resistance, °F.	170°
Water absorption, % by weight, 48 hours	0.4-0.6
Volume resistivity, ohm-cms (50% relative humidity and 25° C.)	10^{12}-10^{13}
Breakdown Voltage, 60 cycles, volts per mil. (instantaneous)	300-450
Dielectric constant, 10^6 cycles	5-7
Power Factor, radio frequencies	1-4.5
Power Factor, 60 cycles	0.10-0.15
Refractive Index Nd	1.5-1.7
Burning Rate	Nil
Effect of Weak Acids	No effect
Effect of Strong Acids	None to slight effect
Effect of Strong Alkalies	Decomposes
Effect of Ageing	Hardens & Yellows
Effect on Metal Inserts	None
Machining Qualities	Excellent
Clarity	Waterclear, Opaque, Translucent
Color Possibilities	Unlimited

MACHINING CHARACTERISTICS

Drilling: High speed vertical drill.

Tapping: On vertical or horizontal machines.

Turning: 450 to 600 RPM regulated to surface speed of 600'/minute. No special tool materials necessary.

Stamping: Roll leaf method usually used.

Cutting: Use abrasion cut-off wheels with water; polish by hand or tumbling.

Polishing: Use double spindle buffing lathe with soft muslin discs.

Grinding: Abrasive form wheels for bevels, radii, other finishing touches not usually included in rough castings.

Sawing: Band saw at 1200' to 1500'/minute using blower and changing saws frequently to cool.

Tumbling: Wet tumbling for very rough articles; dry tumbling is equivalent to ashing and most frequently used; grease or wax tumbling produces high lustre.

SHAPES AVAILABLE FROM STOCK MOLDS

Rods: Round, fluted, square, four-leaf clover, scalloped, eight-corner "square", three-leaf clover, oval, three point, octagonal, half round, quarter round, hexagonal.

Rectangular shapes • Sheets and slabs
Cylinders • Sheets between glass

—All in wide range of sizes, lengths and/or diameters.

Many open special shapes are also available, such as: cutlery handles, kitchen utensils handles, pipe stems, clock cases, automotive trimmings, furniture trims, lamp parts, jewelry items, buttons, many others.

SPECIAL CASTINGS MADE TO CUSTOMERS' SPECIFICATIONS

If you desire castings which are not available from stock molds, special shapes can be made to your specifications, providing draft is all one way. Such special molds can be designed and produced quickly—within three weeks—and at a cost far less than for any other type mold.

ENGINEERING SERVICE

For further detailed information covering any of the above, consult the Marblette engineering staff which offers its services and counsel to help solve your problems. Years of extensive experience with all types of production problems have qualified them to assist you.

Which of These "Poly-Eth" Resins Can Solve Your Problems Best?

Proven in countless applications, Spencer "Poly-Eth" molding resins are available in standard or custom-made grades. See us for a resin to fit your specific molding needs.

New "Poly-Eth Hi-D" (right) withstands 240° heat. Has density of .935. Ready in commercial quantities for film, molding, other uses.

New glass-clear "Poly-Eth" resins make film that's twice as clear as conventional polyethylene. Has higher gloss, is stiffer and easier to handle. Tailored to your own needs in both blown and flat film.

No matter what your needs, it will pay you to investigate Spencer "Poly-Eth" resins. Spencer has a full range of polyethylene resins with a variety of densities and properties.

Not only that, but Spencer's fast delivery and expert Technical Service can help you eliminate your raw material problems. For full information, contact the Spencer office nearest you.

DU PONT

DU PONT

TEFLON®

FLUOROCARBON RESINS

application:

Extreme chemical inertness, resiliency and toughness are the properties of TEFLON resins that make them especially suited for such applications as the pump bearing parts shown below. When these submersible pumps are used for pumping certain chemicals, TEFLON resins are the only materials that will resist corrosion and give long, efficient service. This assembly is one of the many crucial components that can be made from TEFLON resins for the handling of corrosive liquids. Other related items include gaskets, packings, valve seats, discs and specially fabricated components of pumps, agitators and mixers.

The high dielectric strength and low heat conductivity of TEFLON fluorocarbon resins make them superior insulation in high frequency circuits, particularly where miniaturization is required. Wire insulated with a TEFLON resin may be of smaller gauge than wire for the same load that is insulated with other materials. Area insulation in electronic equipment may be thinner and lighter due to the ability of TEFLON resins to withstand heat and prevent current leakage.

Bearing assembly of TEFLON tetrafluoroethylene resins in submersible pump resists chemical attack and needs no lubrication.

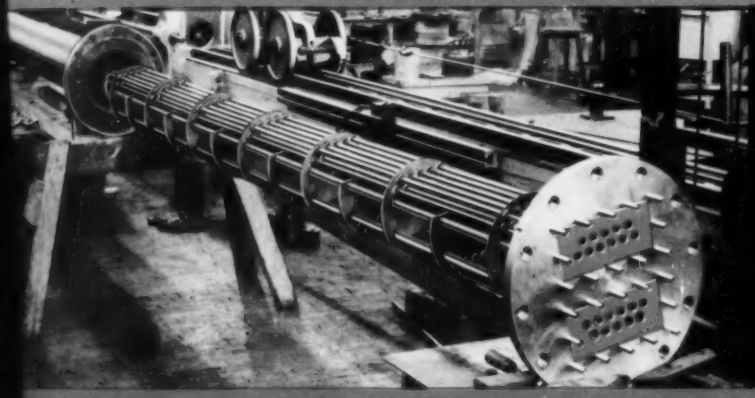
description:

TEFLON is the Du Pont registered trademark for fluorocarbon resins, engineering materials that are unique in their ability to resist chemical corrosion, to provide heat and electrical barriers of maximum efficiency, to resist penetration by or absorption of water, to resist adhesion, and to minimize friction.

TEFLON fluorocarbon resins are supplied in three forms: in molding powders, extrusion powders which are compounded with an organic extrusion aid, and in aqueous dispersions. The general purpose molding powders are granular powders of about a 30 mesh size.



When fabricated into tape, sheets, rods, cylinders, wire and fabric coatings, laminates or various parts, the material has a waxy appearance, and has the same slippery feel. Surfaces of TEFLON resins are so anti-stick that TEFLON resins are used to coat bakery rollers and other food equipment to prevent sticking and eliminate greasing of utensils.

Coatings formed on surfaces by applications of the enamels based on TEFLON resins provide the same surface properties as are available in massive fabricated forms.

properties:

TEFLON fluorocarbon resins are inert to nearly all chemicals and solvents normally used in commercial practices. An exception to this is metallic sodium and the other alkali metals. At elevated temperatures and pressures, halogens and certain halogenated chemicals and solvents may affect TEFLON resins.

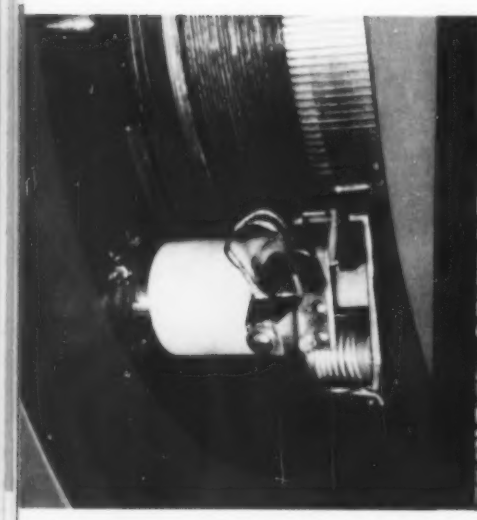
Thermally, TEFLON tetrafluoroethylene resins are exceptionally stable, and may be used efficiently in applications that must withstand temperatures as low as —450°F. or as high as 500°F. The combina-

Grommets and gaskets of TEFLON resins support the tubes in this heat exchanger, which raises the temperature of strong nitric acid to 350°—375°F. Parts also prevent galvanic action which could destroy the tantalum tubes.

Packings of TEFLON resins provide uniform performance and long service life. They are impervious to liquids and gases. The low coefficient of friction of TEFLON resins not only reduces torque, but also increases mechanical efficiency.

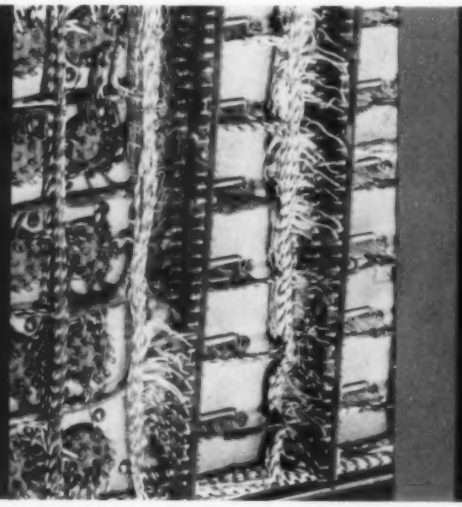
Envelope gaskets of TEFLON tetrafluoroethylene resins consist of a soft filler covered by a jacket of TEFLON. They are used for sealing large diameters and where bolting pressures must be limited, as in glass-lined equipment and in pipe made from ceramic materials.

tion of this unusually broad temperature range with a low loss factor and a high dielectric strength makes TEFLON resins unique for high frequency insulation.



The waxy texture of TEFLON provides a surface so non-adhesive that even the stickiest and most viscous materials will not adhere permanently to it. The friction between two surfaces of TEFLON is as low as that of ice rubbing on ice. Kinetic coefficients of friction as low as .04 have been measured between surfaces of TEFLON. A useful trait of TEFLON resins is their tendency to deposit a molecular film on other materials rubbed against them. A very thin film of a TEFLON resin is thus developed on the opposing surface, and the resulting bearing of TEFLON on TEFLON is virtually frictionless.

TEFLON resins alone may be used as bearing materials in applications where bearing loads are low. Higher load bearing capacity may be achieved by reinforcement with other materials.



In addition to these dominant qualities, TEFLON resins are exceedingly tough, completely unaffected by outdoor weathering, have good impact strength over the entire temperature range, and are relatively flexible.

forming and working:

Because TEFLON resins do not melt and flow, molding techniques used on them must be different from those used on the more common resins. TEFLON resins are formed by a modification of compression molding techniques in which the material is first cold formed, and then sintered at high temperatures. Extrusion techniques have been developed in which the forming of rods, bars and tubes and the sintering

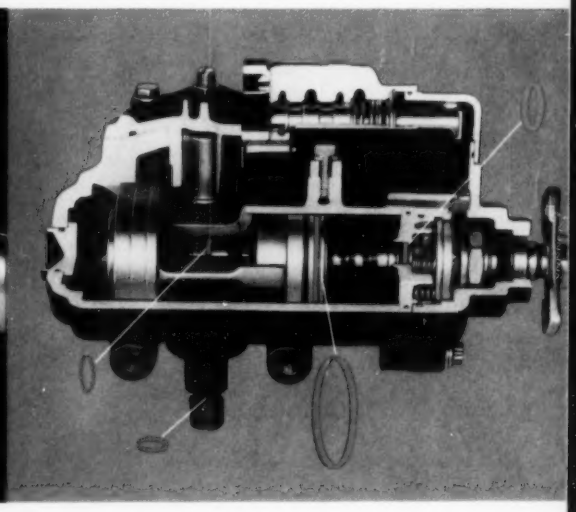
TEFLON resins have been found the ideal materials for use in the brushholder sleeves for this motor-generator, which is used in high-speed freight train service, because of their high short-time dielectric strength.

Wire coated with TEFLON 6 provides outstanding service in electronic units and components such as this amplifier and computer for automatic pilot and automatic flight control system.

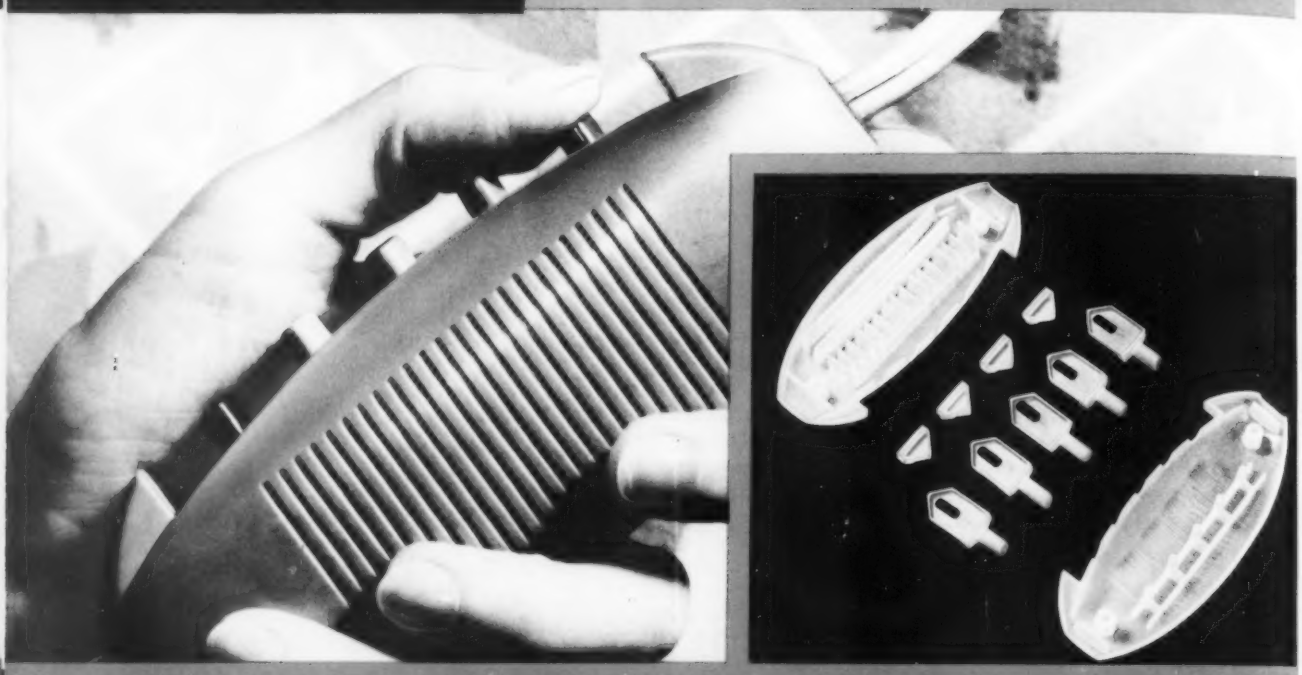
Lead-through bushings and connectors of a TEFLON resin have excellent corona, arc and ohmic resistance, maintaining their seal when cycled repeatedly over a wide range of temperatures.

of them are accomplished as consecutive stages in the same operation. In the formation of large sheets of TEFLON, billets and certain special shapes, the powder is formed in one operation, and sintered in a second operation. Thin sections of TEFLON may be made by a new process in which a lubricated paste of a TEFLON resin is extruded. Tape and coated wire may be produced by calendering. Tape may also be made by skiving sheet from cylinders and then slitting it.

Complex shapes may be produced by machining rod and tube stock. Where desirable, TEFLON resins may be colored by the addition of pigment to the powders before they are formed. A variety of pigments is available to provide colors and shades. An ample range of colors may be obtained to accommodate color coding systems on wire for electrical and electronic circuits.



A hose assembly lined with a TEFLON resin transmits 80-octane fuel to the engine of this 1-man helicopter. The hose withstands subzero temperatures and tropical heat and humidity, and is unaffected by torsion and vibration.



Water meter pistons of TEFLON tetrafluoroethylene resins assure accurate meter readings. The low coefficient of friction allows parts to move freely.

New heat and acid-resistant seals of a TEFLON resin check high pressures in drill pipe joints. Ring seals made of TEFLON tetrafluoroethylene resins prevent leakage at pipe joints.

Piston ring, seals and lockwasher of a TEFLON resin reduce manual turning effort and wear in this power steering mechanism. A TEFLON resin was selected because of toughness, low coefficient of friction, and thermal stability.

Heating pad switch of tough, resilient ZYTEL has simple, attractive exterior, intricately molded interior.

application:

Extraordinary mechanical strength, high surface hardness, ease of forming and low coefficient of friction, all major qualities of ZYTEL make this nylon resin a highly efficient material for such applications as guide shoes for elevator cars. Parts made of ZYTEL need little or no lubrication. Mass production is economical, and long and satisfactory service life is the rule.

When unlubricated gears of resilient ZYTEL are used, they are not subjected to the abrasion from hard particles which often collect in lubricants used with steel drives. ZYTEL is an effective material for making cams, shafts, worm gears, mechanical linkages, couplings and conveyor chains. Unlubricated in many of these applications, the resin is also highly resistant to solvents and chemicals. Components of ZYTEL operate efficiently at temperatures up to 250°F.

The dielectric strength of ZYTEL nylon resin adapts it to use in such applications as injection molded coil forms for electrical equipment that operates at commercial frequencies.

description:

ZYTEL is the Du Pont registered trademark for a versatile group of durable polymeric amides, noted for extreme toughness and strength.

Numerous formulations of ZYTEL nylon resins are available. All types of ZYTEL are supplied by Du Pont as molding powders; all compositions of ZYTEL are thermoplastic. The most common method of fabricating parts of ZYTEL in mass production is by the use of injection-molding equipment.

Rod and stock forms of ZYTEL are readily available from processors; from these forms parts may be machined or otherwise fabricated in the conventional manner. ZYTEL 42, a newly developed member of the family, has a viscosity especially tailored for extrusion. Some of the compositions of ZYTEL are available in a variety of colors. Parts of ZYTEL nylon resin may also be colored by immersing the parts in a boiling solution of dyes, such as those used for dyeing of household fabrics.

Of interest also is weather-resistant, black ZYTEL 105 especially developed for outdoor use.

properties:

ZYTEL is superior to conventional thermoplastics in that it does not show such pronounced decreases in tensile strength or increases in plastic flow at temperatures that approach its molding temperature. High temperature nylons are crystalline and have sharp melting points above which they are as fluid as a light lubricating oil. ZYTEL has a high impact strength, and excellent flexibility at temperatures as low as —40°F. High temperature operations should be held below 250°F. for continuous service. Electrically, ZYTEL is suitable for all insulation applications at commercial power frequencies, especially in instances in which mechanical strength and toughness are needed in addition to insulation properties.

ZYTEL is highly effective in cam and gear applications because it is resilient, abrasion resistant, strong, and has a low coefficient of friction. Where stresses are concentrated on small areas of gears made of ZYTEL, the resiliency of the resin permits a temporary deformation that distributes the load over a larger area. When the load is removed, the gear recovers its original form. In most gear applications, ZYTEL can be used without lubrication.

When lubrication must be used, a variety of lubricants other than oil and grease may be employed

ZYTEL nylon resin makes possible durable, non-shattering, colorful new designs for aerosol containers. A newly developed grade, ZYTEL 42, and a new fabricating technique are responsible for the entrance of ZYTEL into the aerosol field.

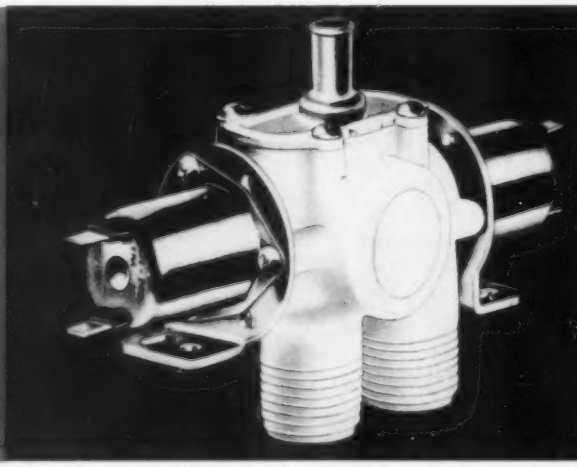
effectively. Many fluids have been found suitable lubricants for ZYTEL, for processes where greases could not be tolerated.

In mechanical applications, ZYTEL damps noise and vibration. ZYTEL is resistant to solvents, being insoluble in common solvents, alkalies, dilute mineral acids and most organic acids. Resistance to alkalies is outstanding.

All formulations of ZYTEL are soluble in phenols and formic acid, and are attacked by concentrated solutions of the mineral acids, but all of the forms are impervious to petroleum oils and greases, lactic acid, and photographic solutions.

forming and working:

ZYTEL nylon resins may be extruded or injection molded either as solid parts or around metal inserts.

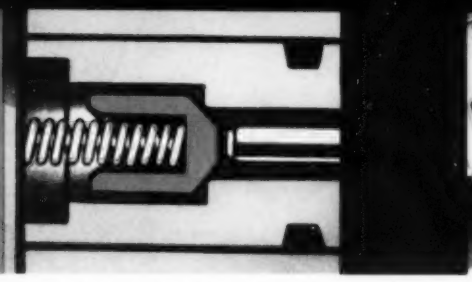


Where ZYTEL is molded to close tolerances that are essential in the finished part—particularly if the finished part has a thin section—the molding process may produce stresses in the resin which should be relieved, to assure long service life and to prevent distortion.

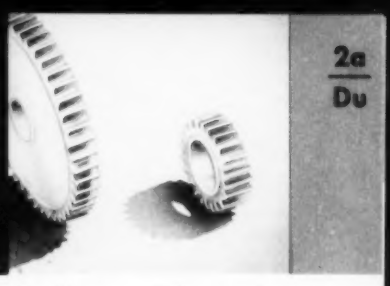
ZYTEL can be applied as jacketing or insulation to wires either directly or over other primary insulating materials.

Stock shapes of ZYTEL can be machined very easily with cutting tools of high speed steel, ground to produce minimum drag. Because ZYTEL is quite tough, cutting tools must be kept sharp, and vibration of the machinery is to be avoided. Where dimensional stability is essential, machined parts should be stress-relieved. The spin-welding technique is also useful for fabrication of ZYTEL nylon resins.

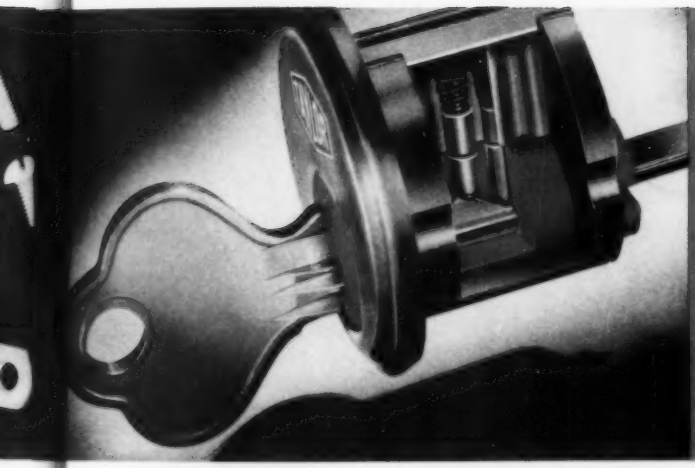
Du Pont ZYTEL nylon resin makes possible attractive, consumer products. This 7-transistor portable radio, for instance, has a virtually unbreakable case of ZYTEL.



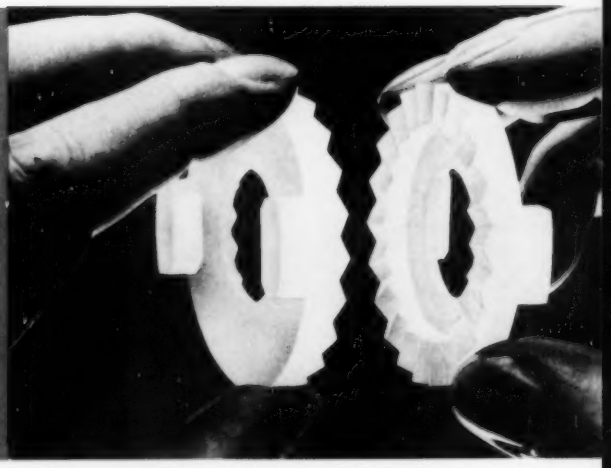
ZYTEL can be molded easily and economically into complex shapes, like the housing for this automatic valve assembly, which is used in modern home washers. ZYTEL makes possible dependable components that require practically no maintenance.



The resilience of ZYTEL keeps vibration from loosening these lightweight, durable, precision-machined fastenings shown above.



ZYTEL bearings and bushings have long-wearing surfaces and excellent impact strength. Because of low coefficient of friction, they need little or no lubrication. They are resistant to oils, gasoline and grease, and are tough and durable.



This leakproof check valve of ZYTEL nylon resin provides a tight seal even where there are slight imperfections in mating parts. It is wear resistant and does not become worn or grooved after repeated contact with the seat.

Sturdy gears of ZYTEL nylon resin not only operate quietly and efficiently, but also damp mechanical vibration. These durable gears can be fabricated economically—either by injection molding, or by machining from extruded bar stock.

The cylinder plug for this door lock is molded of DuPont ZYTEL nylon resin. The corrosion-resistant, weatherproof cylinder plug will not stick, and is not subject to electrolytic action. In addition, lubrication is not necessary, and long service life can be expected.

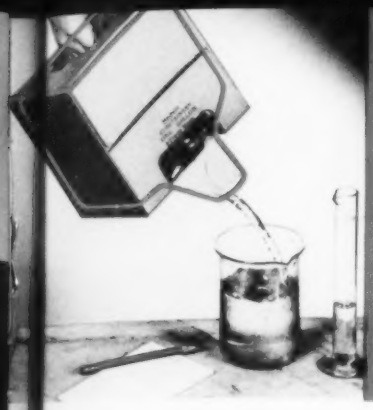
These clutch facings of ZYTEL revolve at 1750 rpm, transmitting 75 in.-oz. of torque, engaging and disengaging continuously 24 hours a day at up to 40 cycles per minute. Yet facings of ZYTEL last nearly six times as long as metal facings.

DU PONT

BETTER THINGS FOR BETTER LIVING THROUGH CHEMISTRY

ALATHON®

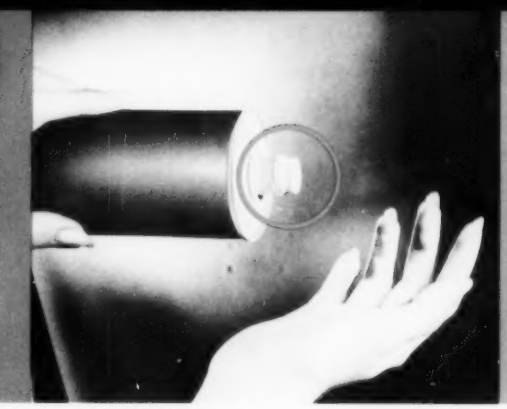
POLYETHYLENE RESINS



Tough, flexible ALATHON makes possible many new, improved products like this squeeze can for a liquid detergent.

application:

ALATHON polyethylene resins are unaffected by mineral acids and most organic solvents. Easily formed into thin sections, ALATHON is well suited for bottles, flasks and flexible tubing for liquid, paste and powdered products. The low power factor of ALATHON, low inductive capacity, inertness to ozone, and excellent dielectric qualities at all frequencies adapt it to wire and cable insulation and jacketing, and many other electrical applications. Its flexibility and durability make ALATHON an ideal material for plastic piping.



ALATHON is available in a wide range of formulations, each having certain outstanding properties which render it particularly suitable for specific applications. Two formulations, marked by superior film transparency, stiffness, impermeability and heat resistance, not only improve the characteristics of finished films, bottles, wire and paper coatings of ALATHON, but also permit use of faster, more economical production techniques. The new ALATHON 31 resin is especially developed for thermo-forming operations.

This container of ALATHON inside a corrugated paper box can be used for shipping, storing and dispensing many liquids. The flexibility, chemical resistance, light weight, and ease of processing of ALATHON make this container effective and practical.

Flexible pipe of ALATHON has outstanding long-term burst strength. It withstands repeated cycles of freezing, varying pressures, and contact with corrosive soil chemicals. It is lightweight, easy to handle—even bends around corners.

Molded of lightweight, unbreakable ALATHON, this nozzle pours freely when the cap is tipped, yet won't drip. The nozzle of ALATHON resists detergents, rust inhibitors, and countless other materials usually packaged in such containers.

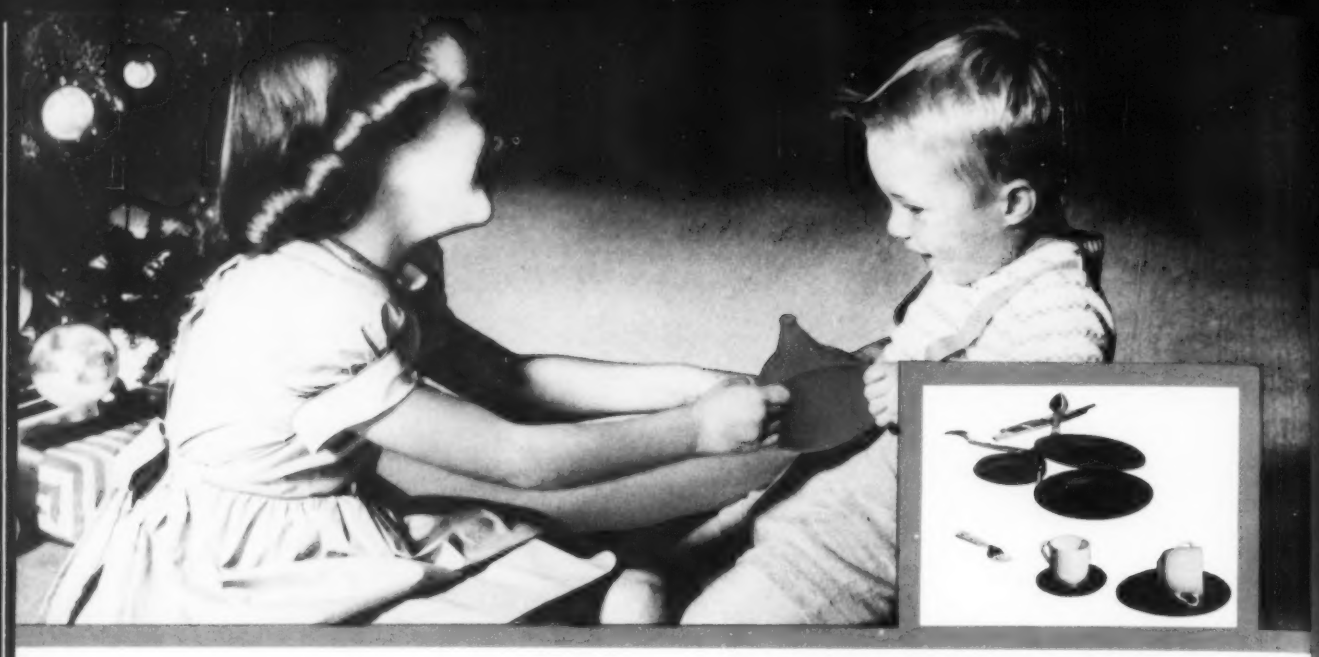
2a
Du

description:

ALATHON is the registered trademark for Du Pont polyethylene resins. The lightest of the commercially available resins, polyethylene has a feel, appearance, and molecular structure similar to that of paraffin wax. ALATHON is supplied by Du Pont, in the form of eighth-inch cubes, to paper coaters, wire extruders, molders and fabricators of film.

The white, translucent resin is non-toxic, essentially odorless and tasteless. It has a low rate of water vapor transmission and low water absorption. Chemically, ALATHON is inert to solvents and most chemicals (including food acids) at room temperatures. It is affected only by certain oxygenated organics, aromatic hydrocarbons and chlorinated hydrocarbons, which cause it to swell at room temperature and dissolve at high temperature.

properties:



The non-polar molecular structure of ALATHON gives it excellent dielectric characteristics at all frequencies. The resistivity of the resin is high, its power factor and inductive capacity are low, and it is comparatively inert to ozone.

ALATHON is inert to many chemical reagents, being substantially unaffected at room temperatures by concentrated hydrochloric, or hydrofluoric acids, for example.

ALATHON remains flexible at low temperatures. It withstands temperatures as low as —95°F. without becoming brittle.

Insulation and jacketing of ALATHON have outstanding electrical characteristics. This wire is easy to handle, lightweight and pliable. The jacket of ALATHON is tough and weather resistant, and has superior heat and abrasion resistance.

Toys, such as this tea set, are safe, attractive and practically indestructible when made of ALATHON. Tasteless, odorless, non-toxic, and water and shock resistant, ALATHON can be molded economically into complex shapes.

A new formulation, black ALATHON 5F is available for film and paper coating, where resistance to outdoor weathering is important.

forming and working:

ALATHON molding powders are fabricated by any of the standard techniques—injection molding, compression molding, or by extrusion. A film of ALATHON may be applied to paper, cloth or other flexible materials by extrusion coating, and sheeting of ALATHON may be vacuum-formed.

Solid shapes of ALATHON may be machined from bar stock, rod or tube with the standard tools and techniques used in working soft metals, and separate pieces of ALATHON can be joined by heat welding, or by spin welding.

Housewares of ALATHON are colorful and shatterproof. Despite its flexibility, ALATHON is strong, even in thin sections. And ALATHON has the virtue of withstanding high temperatures—these wares can be sterilized in scalding water without damage.

Pop this convenient pouch package into water. Cook with no trace of food odor. Cool and serve. This new food package consists of three layers: printed aluminum foil, a special 15-lb. paper, and a one mil interior coating of a Du Pont ALATHON resin.

Here a coating of ALATHON, permanently bonded to the aluminum jacketing of industrial pipe, provides protection against moisture and acid fumes. Without ALATHON, installation of such pipe in corrosive atmospheres would be impractical.

DU PONT

LUCITE®

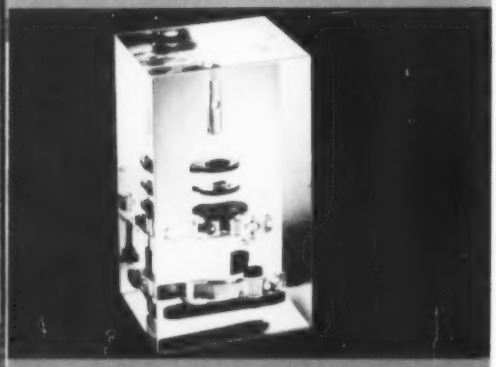
ACRYLIC RESINS

2a
Du

Control panels for this new washer and dryer are molded of durable, crystal-clear, sparkling LUCITE.

application:

Due to its outdoor stability and optical characteristics, LUCITE has wide application on architecture, signs and displays, and lighting. Lighting surfaces of LUCITE provide high visibility without glare. Smooth, ribbed or pebbled surfaces of LUCITE in curved or flat sections can be formed to give unusual yet efficient lighting effects.



LUCITE acrylic resin can be colored, or sheets of LUCITE can be back-painted, for use in signs. It can be extruded in any desired length for effective designs of indoor or outdoor signs.

Extraordinarily strong, and capable of being economically injection molded to close tolerances, clear LUCITE can be used as an optical lens material. It comes in gemlike colors for such automotive uses as tail-light lenses and parking lights; for use in decorative emblems and parts for appliances; for specialty packaging and jewelry applications.

LUCITE is supplied by Du Pont in several formulations, each having properties which suggest specific applications. One of the newest formulations permits molding temperatures 30°F. to 50°F. higher than previous acrylic resins, with increased fluidity during processing, and improved stability after. Yet it retains the beauty and weather resistance which characterize all products made of LUCITE.

Because it is made of LUCITE, the case of this electric razor will retain its jewel-like appearance for years.

Products are embedded in LUCITE for instructive and attractive exploded-view effects such as this one.

Optically designed indoor lighting fixtures of LUCITE provide low brightness with even diffusion of light.

750 luminaires of LUCITE on this 7½ mile stretch — longest fluorescent street-lighting installation in the world.

description:

LUCITE is the registered trademark for Du Pont acrylic resins. LUCITE is available in a range of molding powders which offer a variety of molding characteristics and properties, and a broad selection of transparent, translucent and opaque colors. The powders are solid and granular, cut to approximately ⅛" cubes for injection molding or shaped in minute spherical granules for compression molding. LUCITE acrylic resins are also available for extrusion.

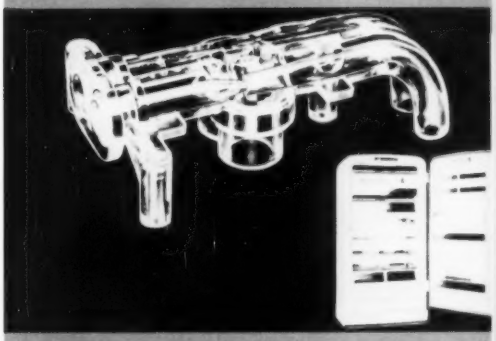
properties:

LUCITE is light in weight—about one-third the weight of glass—with relatively high impact strength, even at low temperatures. LUCITE can be injection molded into patterns of extreme intricacy. Moldings of LUCITE are form-stable at temperatures of 200°F. and, in some cases, higher. As with other thermoplastics, however, the tensile strength of this resin decreases with severe temperature increases.

LUCITE has a low thermal conductivity, about that of rubber. Its coefficient of linear thermal expansion is about eight times that of steel, and ten times that of glass.

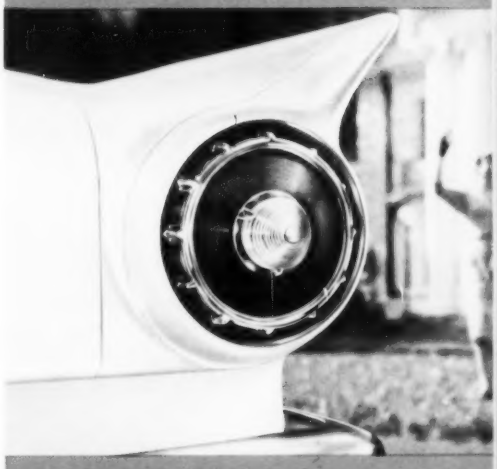
LUCITE has superior optical properties. It transmits 92% of the light striking it. This clarity is not diminished by age, sunlight or moisture.

The combination of this transparency with a highly polished surface finish enables LUCITE to "pipe" light with very little leakage, around angles as acute as 42°, or curves with radii three times or more the thickness of the material. "Edge-lighting" effects



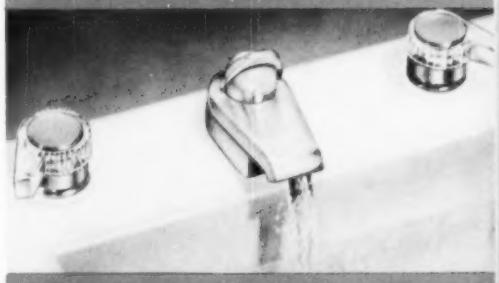
are also possible with LUCITE. LUCITE has outstanding dielectric strength, does not track, and has exceptional corona resistance. Because these properties are relatively unaffected by weather or aging, insulations of LUCITE will give long, effective service.

Chemically, LUCITE is resistant to dilute alkalies, many strong acids, and numerous organic chemicals. Most impressive is its resistance to water. The strength and toughness of LUCITE are virtually unaffected by immersion in either water or water vapor. LUCITE is odorless, tasteless, non-irritating, and non-toxic.



forming and working:

Molding powders of LUCITE may be fabricated either by injection or compression molding, or by extrusion. Molded LUCITE may be shaped with woodworking equipment in much the same fashion as wood or soft metal. LUCITE may be sawed, punched, stamped, drilled, threaded, routed or formed. Pieces of it may be joined either by cementing or by heat-welding. LUCITE may also be bonded to other materials with suitable commercial adhesives. Parts of LUCITE may also be assembled by spin-welding. A good joint between two pieces of LUCITE is strong, transparent, and practically invisible.



LUCITE may be decorated with paint, stains, silk screen designs, or by sand-blasting, carving or etching. To obtain stable colors, certain pigments or dyes may be added to powdered LUCITE, before it is molded. In addition, LUCITE acrylic resin is supplied in a range of transparent, translucent and opaque colors.

LUCITE is readily molded into complex shapes like this juice-mixing valve for a refrigerator. Its sparkling clarity makes the valve easy to inspect for cleanliness. LUCITE resists chemical action of fruit juices and other food substances.

Parts molded of LUCITE make a major contribution to today's smartly styled, efficiently designed automobiles. This handsome, durable tail-light lens of LUCITE adds a note of distinction to a popular model. Its inner surfaces are molded to precision contoured lenses.

The sparkling clarity of Du Pont LUCITE acrylic resin adds beauty to these plumbing fixture knobs. The toughness, transparency, durability and eye appeal of LUCITE help designers develop original new products.

Du Pont engineering materials

At Chestnut Run, Delaware, Du Pont maintains its Polychemicals Sales Service Laboratory, where continued study of basic plastics engineering materials occurs. The laboratory enables Du Pont to help molders and end-users improve processing techniques, to continue to improve the various properties of the above materials, and to investigate new uses for them. This building contains 62,000 square feet and is equipped with the most modern and efficient apparatus and equipment available.

Zytel®
NYLON RESINS

Alathon®
POLYETHYLENE RESINS

Lucite®
ACRYLIC RESINS

comparative characteristics chart

chemical	*mechanical*	*electrical*	*structural*	*decorative*
Completely inert to all chemicals and solvents normally encountered in industry. Impervious to water.	Tough over a range of temperatures from — 450 to + 500° F. Non-adhesive. Low friction coefficient. Self-lubricating.	Outstanding in all electrical properties at all frequencies.	Tough and resilient. Resistant to impact. Impervious to weather.	Can be colored. Useful for color coatings to aid identification.
Unaffected by common solvents, alkalies, dilute mineral acids and most organic acids.	Tough and resilient at low temperatures. Requires little or no lubrication. Resists abrasion.	Good dielectric properties at commercial power frequencies.	Strong and durable. Good form stability. Light in weight.	Good color possibilities. Attractive texture.
Excellent chemical and water resistance.	Tough and flexible over wide range of temperatures.	Excellent dielectric properties over wide frequency and temperature range.	Good strength and toughness. Free from taste, odor and toxicity. When black pigmented resists weather. Resists impact. Very light weight.	Easily colored. Attractive translucent texture.
Resistant to dilute alkalies, many strong acids and other chemicals.	Rigid. Good dimensional stability.	Good dielectric properties at all commercial power frequencies.	Unexcelled weatherability. Shatter resistant. Good dimensional stability. Light in weight. Free from taste, odor and toxicity.	Transparent. Available in range of colors. Transmits and "pipes" light. Unusual beauty.

footnotes Tests have been performed by A.S.T.M. methods unless otherwise indicated. Data shown are average values and should not be used for specifications.

*Test not applicable.

(1) Other compositions of "Teflon," "Alathon," "Zytel," and "Lucite" are available for special requirements. The types shown here are the most widely used at the present. The properties shown here apply to standard compositions.

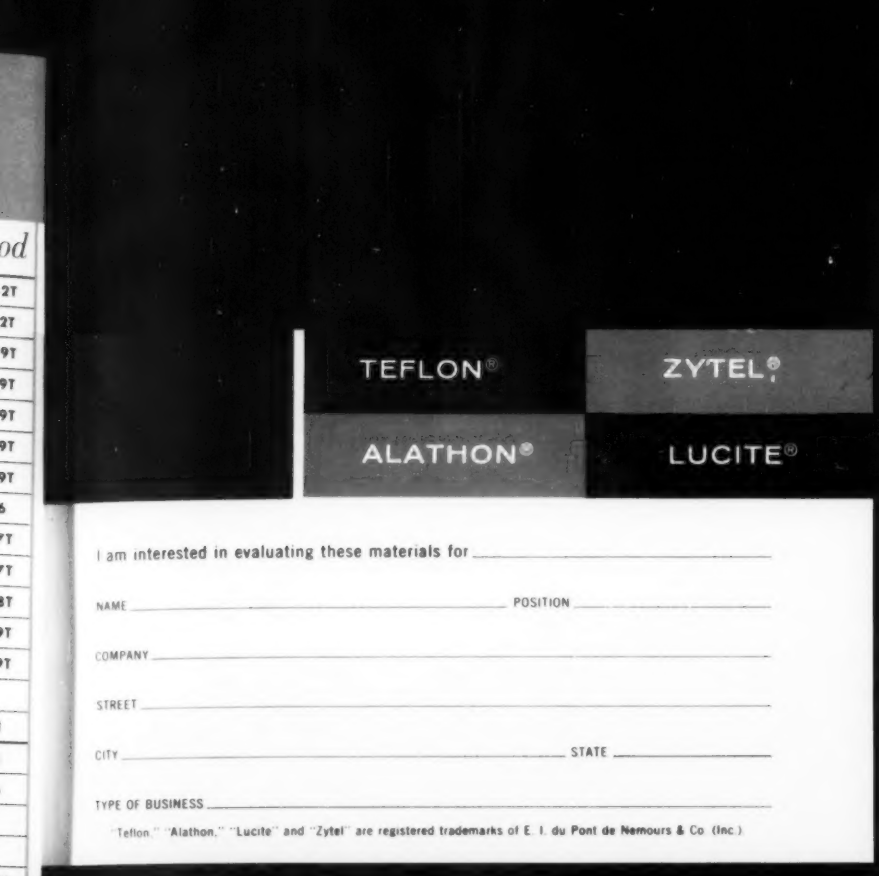
(2) "Alathon" 5 differs from 10 in the fact that the former contains an antioxidant.

(3) Hardness of "Alathon" and "Teflon" determined by Shore durometer, A.S.T.M. method D676-49T.

(4) Term "creep in flexure" is a measure of the deformation under a prolonged standard load. Results here represent mils deflection in 24 hrs. of a ⅛" x ½" bar, 4" span, center-loaded flatwise to 1000 lb./sq. in., minus the initial deflection.

(5) Thermal conductivity measured by Cenco-Fitch apparatus.

(6) Deformation under load for "Alathon" determined at 100 lb./sq. in. (standard for non-rigid plastics).



(7) The outdoor durability of black-pigmented "Alathon" is excellent.

(8) Tensile strength in oriented film may be as high as 15,000 lb./sq. in.

(9) Value is 1000-2000 volts/mil in thicknesses of 5-12 mils.

(10) Softening point, Vicat.

ACRYLIC RESINS

The applications shown in this booklet are uses in which the outstanding qualities of the respective resins are illustrated.

To find which of the resins will best suit your needs, project the basic features of these applications to the problems your products involve.

For more information, call the nearest Du Pont district office, listed on page 16. Or contact E. I. du Pont de Nemours & Company, Inc., Polychemicals Department, Wilmington 98, Delaware.

Spin-welding, an unusual but relatively simple fabricating technique for plastics, recently improved and applied to new applications at Du Pont's Sales Service Laboratory near Wilmington, utilizes frictional heat, generated by the rotational rubbing of two surfaces, to melt and join them together.

This improved technique works especially well with thermoplastic materials such as Du Pont ZYTEL® nylon resin, LUCITE® acrylic resin and ALATHON® polyethylene resin.

The Du Pont Company assumes no obligation or liability for any advice furnished by it, or results obtained with respect to these products. All such advice is given and accepted at the buyer's risk. Du Pont warrants that the materials themselves do not infringe the claims of any United States patent, but no license is implied; nor is any further patent warranty made.

Acrylics

BY F. J. GLAVIS* and HELEN F. TUCKER*

Acrylics constitute a family that comprises monomers and polymers of acrylic, substituted acrylic, and methacrylic acids, their salts, esters, and other derivatives, such as nitriles and amides.

Acid monomers and polymers: Acrylic acid, $CH_2 = CHCOOH$, is a corrosive, weak acid, available in essentially anhydrous form (glacial). Reactions of acrylic acid are typical of normal acid functions (ester, salt, anhydride, and acid chloride formation) and of the unsaturated function (addition of halogens, amines, mercaptans; Diels-Alder reaction). All reactions are qualified by the polymerizable nature of the molecule.

Polyacrylic acid, available as an aqueous solution in different viscosity grades and as an anhydrous powder, is a water-soluble polymer that gives hard, brittle, clear films. This product is capable of undergoing chemical reactions involving the acid function, such as salt formation and esterification, insolubilization being achieved in the latter instance by the use of polyfunctional alcohols.

Methacrylic acid, available in anhydrous form, is similarly amenable to reaction of the two functional groupings in the molecule as well as to polymerization.

Both acrylic and methacrylic acid are used in the modification of the properties of polymers through incorporation of varying amounts of these monomers in copolymerization reactions. Improved hardness, solvent resistance, and increased hydrophilicity may be obtained. Introduction of the acid group permits vulcanization of the polymer with zinc oxide.

Salts: Monomeric salts may be prepared by neutralization of the corresponding acid or by suitable saponification of the appropriate monomeric ester. Solid sodium methacrylate is currently available.

Polymeric acrylic salts may be prepared by 1) neutralization of the polymeric acids; 2) polymerization of the monomeric salts; 3) saponification of the polymeric acrylic esters; and 4) alkaline hydrolysis of the polymeric nitrile. For example, sodium polyacrylate made by the saponification of polyacrylonitrile is available from many sources. The potassium and ammonium salts are also produced. The polymeric salts are water-soluble polyanionics, giving hard, brittle, clear, hygroscopic films. In the presence of other cations, they show ion-exchange reactivity. The presence of acrylic salts as components of a copolymer system may affect the properties of the product so formed by alteration of the hydrophilic nature of the polymer, by insolubilization with polyfunctional cations, or by modifying hardness and brittleness.

Esters: A wide range of monomeric acrylic esters is available, with large quantities of methyl and ethyl acrylates and methyl methacrylate now being produced. Other available esters include butyl, 2-ethylbutyl, 2-ethylhexyl, octyl, methoxyethyl, ethoxyethyl, 3-ethoxypropyl and 2-diethylaminoethyl acrylates and ethyl, butyl, hexyl, decyl-octyl, lauryl, stearyl, 2-dimethylaminoethyl, and 2-diethylaminoethyl methacrylates. These esters are capable of undergoing reactions of the ester group, and of the unsaturated system, including polymerization. Variation of the molecular make-up of copolymers, involving different acrylate and methacrylate esters as well as other polymerizable monomers, permits wide variations of physical properties.

The polymeric esters may be considered from the point of view of these polymerization methods:

1) The monomeric esters can be

* Research Laboratories, Rohm & Haas Co., Washington Sq., Philadelphia, Pa.

Recent Developments and References were prepared by the editors.

By switching from glass to acrylic glazing (*Plexiglas*, Rohm & Haas Co.) for the drop side-window in the motorman's cab of suburban multiple-unit cars, the Pennsylvania Railroad is saving $3500 a year in replacement costs. The lightweight plastic panes also facilitate opening and closing.

A new line of cast acrylic sheet (*Larcrylic*, Larc Products, Inc.) is produced in clear, white, and colors in standard sizes from 48 by 48 to 100 by 120 in., 0.06 to 0.375 in. thick.

An improved methacrylate molding material (*Lucite 140*, Du Pont) has a heat stability that permits molding at temperatures 40° higher than was formerly possible. The higher heat stability of the resin permits one of three possibilities: 1) speed-up of the molding cycle; 2) filling of more complicated molds; or 3) reduction of pressure to eliminate flash.

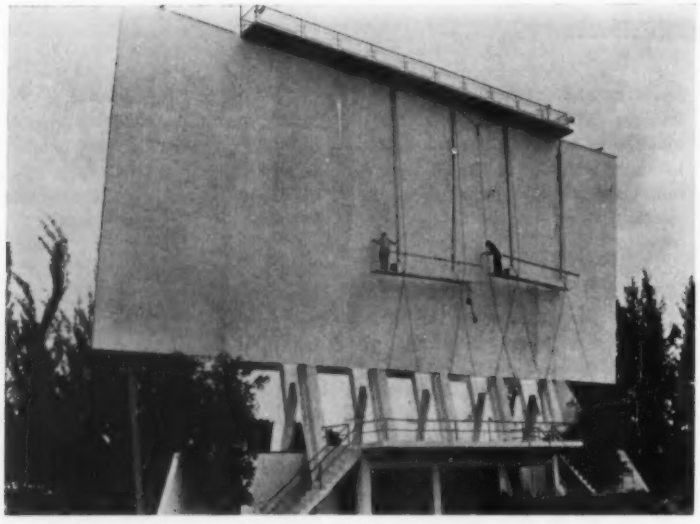
Acrylic resin molding powder (*Lucite*, Du Pont) is now available in diamond-shaped pellets, ⅛ in. long and ⅛ in. thick. The new shape improves pouring, handling by pneumatic hopper loaders, and metering into extruders and injection molding machines. It gives greater shot-to-shot uniformity of injection molded parts and saves space in packing and storing. It has approximately 10% higher bulk density than cube-cut powder and lower moisture content, making possible processing at higher temperatures without bubbling or splay in molded parts. A virtual absence of fines helps prevent discoloring under heat.

Cast acrylic sheets (*Plexiglas RL*, Rohm & Haas Co.) in sizes up to 8½ by 10 ft. are furnished in both colorless transparent and in translucent colors. These large sheets are used for internally illuminated signs, large-area glazing, fluorescent light diffusers, dome skylights, and other architectural applications. They have the same surface standards and optical quality as commercial grade, untrimmed, unmasked acrylic sheet (*Plexiglas R*) and also the same physical, chemical, and weathering properties.

A new cleaner and polisher (*Acrakleen*, Schwartz Chemical Co., Inc.) improves pilot vision by removing fine scratches and haze from plastic windshields on aircraft and boats. The product is effective on all kinds of plastics, including acrylics, polystyrene, acetate, and vinyls.

A new acrylic lacquer (*Resolac*, Resolite Corp.) restores luster to weather-dulled reinforced plastics panels. The lacquer, composed of acrylic resins in an organic solvent, can also be used to deepen the color, reducing light and heat transmission.

High-solids acrylic thickeners and dispersants (*Acrysol ASE-75* and *ASE-60*, Rohm & Haas Co.) can be converted at the point of use to a dilute viscous salt, thus reducing shipping costs and simplifying handling. One type (*ASE-75*) will be used in the manufacture of paints, inks, adhesives, paper coatings, textile backings, floor finishes, grinding compounds, and other applications for which dry powders or low-solids thickeners are now used. It will also be used to advantage in the areas where polyacrylates are now employed. Solutions of ASE-60 suspend pigments, abrasives, and other divided solids.



polymerized in bulk by casting techniques to give sheet materials.

2) Suspension polymerization of the monomeric esters has been used to prepare molding powders. The polymer can be produced in discrete particles of well-defined dimensions by control of the polymerization conditions. The molding powders are formed into hard, transparent, clear objects by applying heat and pressure in dies of the desired shape.

3) A third method involves the polymerization of acrylic esters in organic solvents. A large range of solvents has been used for the preparation of soluble polymers, the properties of which permit application in coating, adhesive, and lubricating oil compositions. By using different esters and combinations of esters, and modifications in the polymerization conditions, polymeric compositions having various solubilities result. These produce films that range from hard and brittle to soft and tacky.

4) By using emulsion polymerization techniques, a fourth type of polymer system has been made available. These stable dispersions of discrete particles of acrylic polymers may form films on drying. Depending upon the particle size of the polymer as well as upon its chemical composition, durable films may be obtained with varying hardness and tack.

Nitriles: Acrylonitrile monomer is readily available from multiple sources. The monomer is a liquid capable of ready polymerization, and is reactive by virtue of both its carbon-to-carbon unsaturation and its nitrile function. Polymerization, which may be effected in aqueous suspension or in solution, provides the basic material for the preparation of fibers (Orlon and Acrilan). Polyacrylonitrile is soluble in such solvents as dimethyl formamide, ethylene carbonate, tetramethylene sulfone, and aqueous solutions of thiocyanate salts, and may be formed into fibers by extruding a polymer solution into a coagulating bath such as water. Polyacrylonitrile may also be hydrolyzed with acid, caustic, or ammonia to form water-soluble hydrolysates as indicated previously in the discussion of polymeric acrylic salts. Acrylonitrile is not amenable to bulk polymerization, since the polymer is insoluble in the monomer. Acrylonitrile is useful in

Acrylic latex paint is applied to face of drive-in theater screen. Paint can take sun, wind, and rain without cracking. (Photo, Rohm & Haas)

copolymer systems to improve such properties as solvent resistance and hardness. Examples include copolymers of acrylonitrile with butadiene, styrene, and vinyl chloride.

Amides: Acrylamide and methacrylamide are available as solid materials. Both the monomers and polymers are susceptible to alkaline hydrolysis with the formation of ammonia and the corresponding acrylic salt. In addition, the amide function can be modified by reaction with formaldehyde to produce methylol acrylamide and methylene-bis-acrylamide, both of which are currently available. Also available is N-tert-butyl acrylamide. Polyacrylamide has been introduced as an industrial flocculant.

Alpha-halogenated esters: The methyl alpha-chloracrylate, derived from methyl acrylate, has been investigated extensively as a material that affords, on polymerization, a hard, clear, transparent sheet with a high softening point and resistance to surface abrasion.

The above chemical classification of the acrylics indicates the wide variety of properties that are obtainable with such materials. There are many instances in which minor proportions of acrylic monomers are useful in modifying the properties of polymer systems based on monomers other than acrylics. The following discussion of end uses will not include materials made with acrylic monomers in minor proportions, such as the butadiene rubbers, and copolymers with vinyl chloride, vinyl acetate, or with styrene.

Design of larger control panels using thin sections is made possible by increased upper molding limit available with new acrylic. (Photo, du Pont)

Applications

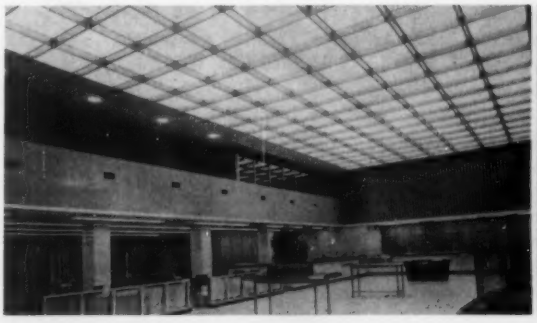
Sheets and molding powders: The properties exhibited by solid acrylic polymers, such as crystal clarity, high impact strength, formability, and resistance to sunlight, weather, and most chemicals, have led to widespread use in military and civilian applications. The fields of usefulness have also been broadened by availability in transparent, in translucent, and in opaque colors.

Acrylic sheet is the standard transparent material for canopies, windows, instrument panels, and searchlight and landing light covers on aircraft. Large sheets, edge-lighted, are used as radar plotting boards in shipboard and ground control stations. To keep pace with the increasingly severe service requirements of pressurized jet aircraft, new grades of acrylic have been developed that have improved resistance to heat and crazing. The stretching technique has made possible enhanced resistance to both crazing and shattering.

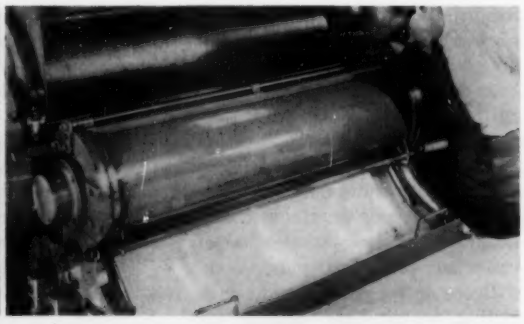
In the general field of merchandising, acrylics have become a major sign material for faces and letters, particularly for outdoor use where weather resistance is important. In addition, acrylics are used for counter dividers, transparent demonstration models of household appliances and industrial machines, display fixtures and cases, and vending machines.

The ability of acrylics to resist breakage and corrosion, and to transmit and diffuse light efficiently makes them beneficial in industrial and architectural applications. Industrial window glazing, safety shields, inspection windows, machine covers, and pump components are some of the uses commonly found in plants and factories. Dome skylights formed from acrylic sheet are an increasingly popular means of admitting daylight through the roofs of industrial, commercial, and public buildings and of private homes. Acrylics are employed to good advantage as the diffusing medium in lighting fixtures and large luminous ceiling areas. Shower enclosures and decorative partitions are other well-established applications. An expanding development is a window glazing panel with integrally formed louvers for the control of sun and sky glare.

In molding-powder form, acrylics are used extensively for the manufacture of automotive parts, such as taillight and stoplight lenses, medallions, nameplates, dials, instrument panels, and signal lights. The beauty and dura-



bility of molded acrylic parts have led to their wide use for nameplates, control knobs, dials, and handles on all types of home appliances, and for pen and pencil barrels and personal accessories, such as hairbrush backs. Covers for fluorescent street lights, jukebox panels, TV implosion shields, and other large-section moldings are being formed from acrylic powder. The extrusion of acrylic sheet from molding powder is particularly effective in the production of thin sheeting. Extruded sheets have also been used in such applications as sign-lighting, glazing, partitions, and shower enclosures.



Advantage is taken of the transparency, strength, light weight, and edge-lighting characteristics of acrylics in the fields of hospital equipment, medical examination instruments, and orthopedic devices. The use of acrylic polymers in the preparation of dentures is an established practice. The embedment of normal and pathological tissues in acrylics for preservation and instructional use is an accepted technique, which has been extended to include embedment of industrial machine parts as sales aids, and the preparation of home decorative articles.

Elastomers: The use of acrylic esters in synthetic rubber formulations may be exemplified by a copolymer of ethyl acrylate with about 5% of a chlorine-containing monomer such as chloroethyl vinyl ether or chloroethyl acrylate. The vulcanized products combine outstanding heat resistance and oil resistance, and have found widest use as gaskets for automatic transmissions for gasoline engines. Vulcanizates of fluorinated acrylics are said to offer advantages in toughness and durability. Acrylate-acrylonitrile copolymers are also being manufactured for use as vulcanizable elastomers. The use of acrylonitrile in the nitrile rubbers continues to offer products of superior solvent resistance and durability. Polyblends of acrylonitrile-styrene resins with butadiene-acrylonitrile rubbers are used for pipes and fittings in industrial applications in which resistance to alkali and acid is required. Polystyrene-acrylonitrile rubber blends exhibit toughness and high impact strength, and impart improved formability to the sheet composition.

Ion exchange resins: Cation exchange resins may be produced by the polymerization of methacrylic acid in the presence of cross-linking agents, such as divinylbenzene. These acrylic-based ion exchange resins are especially adaptable for sodium therapy, for pharmaceutical applications that involve the recovery of antibiotics, and in the treatment of sugar solutions. In the latter application the weak acid character of the resin does not cause the inversion of the sucrose.

Textiles: Considerable work has been undertaken to overcome certain difficulties encountered in the acrylic fibers, such as Orlon and Acrilan. Fiber studies have been concerned with modifications in molecular formulation to achieve greater dye receptivity, and mechanical modifications to reduce fibrilation and subsequent apparent color variations in dyed fabrics. Blends of polyacrylonitrile with such fibers as wool, rayon, and acetate provide a means of obtaining mixed fibers with the

Lighting and glazing applications—both indoors and outdoors—stand out as major market for acrylic materials. Typical indoor applications include large-area luminous ceiling made up of diffusing panels extruded of acrylic (top, left) and sight panels formed of clear acrylic sheeting that protect materials being processed while permitting continuous inspection (top, right). Outdoor applications include formed signs silk screened in multiple colors (left) and 6-ft. molded acrylic enclosures for fluorescent lights used to illuminate bridges, highways, etc. (right). (Photos, Rohm & Haas)

dyeability and other properties characteristic of the fiber types present in the blend. Certain synthetic fiber blends have been developed to simulate fur. Modification of cotton to give improved characteristics, such as fungus resistance and higher heat resistivity, has been achieved by treatment of the cotton with acrylonitrile.

Acrylics are established materials for sizing of fibers, with polyacrylic acid used extensively in the nylon field. Acrylate dispersions provide highly desirable types of finishes. Applied to cotton and rayon, they contribute a firmer hand, improved tensile and tear strength, and better abrasion and wear resistance. They are not easily removed by washing, hence are durable finishes. Uses of an acrylic backing for upholstery fabric is an established practice. Acrylic dispersions have also found application as binders for nonwoven fabrics.

Coatings: Acrylic emulsion paints constitute a major expanding development. Specifically recommended for durability of finish, lack of odor, speed of drying, and ease of application, both the emulsion and compounded paints for interior and exterior use in pigmented formulations are available. Some formulations have been suggested for use over damp surfaces. Exterior use over masonry is an expanding application. Acrylic automotive finishes represent a promising field of application. Enhanced durability of the finish and prolonged retention of luster are achieved, particularly with the newer pastels. A thermosetting acrylic-base coating for appliances is also available.

For application by either spraying or brushing, acrylic-coating solutions in organic solvents are available in types that give almost any desired range of hardness or tackiness, with clarity and durability a prominent feature of all these coating materials. These acrylic coatings are for both decorative and protective uses, the scope of application ranging from protection of art treasures to resin treatment of raincoats. Decorative and metalized coatings can also be applied to plastics articles to enhance their appearance. Other coating applications include the use of water-soluble acrylic polymers in the thickening of resin-based coating formulations to a predetermined viscosity. In addition, such acrylic monomers as tetraethylene glycol dimethacrylate have found application in the preparation of coating and filling compositions and as vulcanizable plasticizers in plastisol formulations.

Paper: Acrylic dispersions are proving to be effective in the coating of paper. They are used for clear, greaseproof coatings, as binders for clay coatings, and as heat-sealing adhesives.

Adhesives: Acrylic monomers find application as components of copolymers used in making pressure-sensitive tapes and bonding agents. They impart improved aging characteristics and adhesion.

Leather: Acrylic dispersions are used in leather-finishing applications. As a base coat for cellulose nitrate and polyvinyl chloride finishes, the acrylics produce permanently flexible and strongly adhering coatings. When dry, these are no longer water dispersible but are soluble in the customary lacquer solvents so that excellent adhesion of subsequent lacquer coatings is obtained. An increasingly widespread use of acrylics in the leather field is as a component of water finishes. In such cases, the acrylic improves the adhesion, flexibility, and leveling of the finish, and depending upon the amount and type used, improves the washability. Improved dimensional stability of drying hides is achieved by the use of water-soluble acrylic pastes.

Soil stabilization: Acrylamide-methylene-bis-acrylamide compositions are being investigated for *in situ* polymerization in soils for such purposes as structural stabilization and impermeabilization.

Transparent gray-tinted protective shield molded of acrylic is placed over screen on television set. (Photo, Rohm & Haas)

Amino Resins

BY HERBERT J. WEST*

RECENT DEVELOPMENTS

A urea-formaldehyde resin (*Uformite F-222,* Rohm & Haas Co.) for baking enamel formulations provides a white baking enamel with improved gloss, hardness, baking speed, and resistance to food stains. The resin also possesses improved adhesion with nondrying alkyds and improved water resistance.

Equipment for continuous production of urea-formaldehyde resin produces about 200 to 300 lb./hr. and is compact in size (W. H. Kreidl). The unit can be installed at the place of use, reducing the cost of the adhesive and eliminating the problem of aging.

A face coat (*Epocal,* Furane Plastics, Inc.) for expendable plaster or gypsum cement casts provides a much harder surface than gypsum cements and will not absorb water after setting. The material, a powdered melamine-urea composition containing fillers and curing agent, also reduces the problem of separating epoxy laminates or castings from the mold.

Triazine resin laminating sirups (*Cyzac,* American Cyanamid Co.) provide protective plastic surfaces on particle board or plywood. One resin (*Cyzac 2352*) is used with paper to provide durable flat working surfaces for tables, dressers, desks, and chests. Another resin (*Cyzac 2247*) is used on laminating papers in conjunction with the above resin to produce decorative surfaces for wood composition board that is to be used as wall paneling, door paneling, or in various "do-it-yourself" applications.

The two most important groups of amino resins are the urea-formaldehyde and melamine-formaldehyde resins. Both groups are thermosetting and cure to colorless, infusible solids, resistant to discoloration on aging or at elevated temperatures.

UREA-FORMALDEHYDE RESINS

Urea-formaldehyde resin sirups were first made, commercially, toward the end of the 1920's. The unmodified cured resins are clear colorless solids which resist discoloration on prolonged heating at moderate temperatures and on exposure to light. White translucent molding materials are made by compounding the resin with purified alpha-cellulose. Colored molding powder is made by the addition of appropriate pigments or dyes. In either of these forms, urea-formaldehyde resin sirups or dried powders have gained major importance in the manufacture of adhesives, in the treatment of textiles and paper, and in surface coatings.

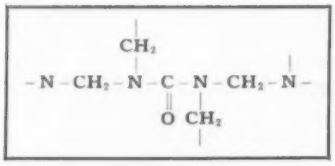
The production of resins from urea and formaldehyde is based on the primary formation of methylol ureas by reaction of formaldehyde with the amide groups. (See Formula 1.) Two moles of formaldehyde may react to produce dimethylol urea.

The methylol ureas condense under slightly acid pH conditions with liberation of water to produce resinous products. The mechanism of the condensation is not positively established, but evidence indicates the formation of three-dimensional structures through methylene cross-linkage. (See Formula 2, p. 92.)

Marvel (J. Am. Chem. Soc. *68,* 1681, 1946) postulates a resin structure containing a network of hexahydro-triazine rings cross-linked by methylene groups. (See Formula 3, p. 92.)

The dimethylol compounds can react with alcohols in the presence of acids to form alkoxy compounds. These compounds condense with liberation of part of the combined alcohol to form resinous products soluble in organic solvents. These resins are used in surface coatings.

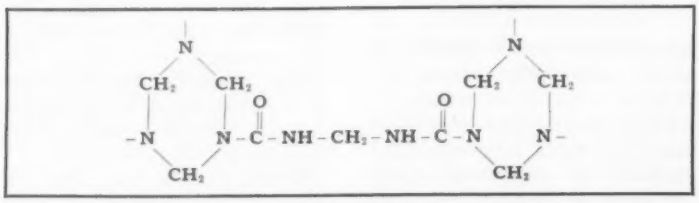
The basic resins are usually clear, water-white sirups or white powdered materials. The dry materials are usually dispersible in water to colorless sirups. Conversion to the insoluble and infusible stage occurs in the presence of acids or materials which develop acidity by reaction with formaldehyde. In most commercial applications the resin is cured by the application of heat. Certain formulations, however, particularly those used as adhesives, can be cured at room temperature by the use of an appropriate catalyst.



Molding compounds

Urea-formaldehyde resins may be compounded with cellulose filler, with or without pigmentation, to form the urea-formaldehyde molding compounds. Urea and formaldehyde solutions are first reacted to form an aqueous sirup. Purified alpha-cellulose is

$$NH_2-CO-NH_2 + HCHO \rightarrow NH_2-CO-NH-CH_2OH$$



FORMULA 1

* Plastics and Resins Div., American Cyanamid Co., 30 Rockefeller Plaza, New York 20, N.Y.
Recent Developments and References were prepared by the editors.

FORMULA 2

Formula 2 (left): Mechanism of condensation reaction used in production of urea involves formation of three-dimensional structures through methylene cross-linkage. Formula 3 (below): Network of hexahydrotriazine rings cross-linked by methylene groups. (See text, p. 91.)

FORMULA 3

added to the sirup and thoroughly mixed in. The white pulp obtained is dried under closely controlled conditions of heat and humidity. The dried material is ground to a fine powder.

At an appropriate stage in the operation, dyes or pigments, lubricants, and catalysts may be added. Usually as a final step in the operation, the powdered material is densified by one of several available methods and the densified product crushed to give the finished molding material in the form of granules.

The unpigmented material gives translucent pearl-white moldings. Colored material gives opaque-to-translucent pastel or full shades, depending upon the type of pigment or dye used.

The molding compounds are usually available in a range of plasticities from very soft to hard. The rate of cure can be controlled during manufacture. Consequently, the molder can usually select a grade of molding material suitable for any specific molding condition. Low-cost grades are available for dark-colored industrial moldings such as electrical parts.

The materials are usually molded within the temperature range of 275 to 350° F. and at pressures ranging from 2000 to 8000 p.s.i. They are more critical to mold than either the phenolics or the melamine-formaldehyde molding compounds. They do not flow quite as readily, and generally set and cure faster in the mold. Both mold-shrinkage and aging-shrinkage values are greater with ureas than with the phenolics.

Largely because of unlimited color possibilities, solvent-, oil-, and grease-resistance, surface hardness, mar-resistance, and so forth, urea-formaldehyde molding compounds are widely used in such applications as cosmetic container closures, buttons, electric mixer housings, and stove hardware.

School desk surfaced with melamine-impregnated decorative laminate can be easily wiped clean of crayon marks. (Photo, American Cyanamid)

Adhesives

Urea-formaldehyde resins have gained wide acceptance for use as adhesives in the plywood and furniture industries. These adhesives can be formulated to cure over a wide range of temperatures. They tolerate a high degree of extension with relatively low-cost material, such as wheat-flour, without serious impairment of the properties of the glue-line.

The resins used as adhesives are usually formulated at a ratio of less than 2 moles formaldehyde to 1 mole of urea.

Urea adhesives cure rapidly at the elevated temperatures used in hot-press operations. When the proper catalysts, as recommended by the manufacturer, are used, excellent bonds are obtained at room temperatures.

Textile and paper resins

Low-molecular-weight urea-formaldehyde condensation products are useful for the impregnation of cotton or rayon textile fabrics to develop improved creaseproofness and other valuable properties. The resin, containing an appropriate catalyst, is cured in the cloth by heating the impregnated goods at temperatures ranging usually from 200 to 250° F. Other types, usually of higher molecular weight, are employed in the various stiffening processes.

Urea-formaldehyde condensation products may be modified to give cationic resin molecules substantive to negatively charged

cellulose fiber. When added in the beater on a paper machine, the resin is almost quantitatively absorbed by the fiber and confers a high degree of wet strength to the finished paper sheet.

Surface coatings

Alkylated urea-formaldehyde resins were first produced commercially in this country in 1936. Their use in surface coatings represented a big advance in the technology of synthetic baking enamels. When used as hardeners with suitable alkyd resins, these solvent-soluble urea resins permit the formulation of enamels that can be baked to almost porcelain-like hardness. These new resins rapidly achieved commercial importance in the production of a wide range of synthetic baking enamels, particularly white enamel for refrigerators and kitchen and hospital furnishings. The finishes are resistant to water, soap, and mild acids, and are characterized by excellent color retention.

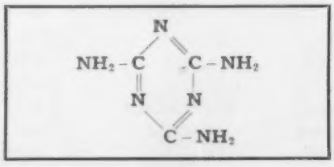
Urea-formaldehyde compound enamels are usually cured at temperatures of 250° F. or above, although formulations are available for cure at room temperature or under forced-dry conditions.

MELAMINE-FORMALDEHYDE RESINS

The most striking feature of melamine-formaldehyde resins is their unusual versatility. Perhaps no other thermosetting materials have as many diverse and valuable applications.

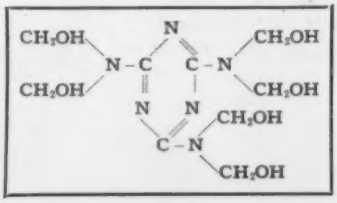
Melamine resins were first introduced to industry in the late 1930's. Today, materials produced from melamine are used in a wide range of important applications, such as critical military parts, industrial and decorative household appliances, high-grade dinnerware and tableware, shockproof laminates for use in naval craft, and decorative laminates for the household and office. They are used in durable boilproof adhesives, in leather tanning, in the treatment of textiles, in the production of wet-strength paper, and in the manufacture of enamel finishes with a high degree of exterior durability.

Chemistry



Melamine may be considered as the cyclic trimer of cyanamide. (See Formula 4.) It is shipped as a white, free-flowing powder and has the following characteristics: Melting point—354° C. (approximately); density—1.57; solubility in water at 25° C.—0.5 percent.

Melamine reacts with 1 to 6 molecules of formaldehyde to form methylol compounds. Hexamethylol melamine can be isolated as a pure crystalline compound with the structure shown in Formula 5.



These methylol compounds can condense to resinous products by mechanisms which are probably similar to those involved in the condensation of methylol ureas. Three-dimensional structures are created with the triazine rings probably cross-linked by methylene groups.

The molding compounds are produced from methylol derivatives containing a relatively low ratio of formaldehyde to melamine.

The cure of the resins is accelerated by acids although it can be accomplished by heat alone under neutral or even slightly alkaline pH conditions. The cured resins are resistant to mild acids, mild alkalies, and boiling water. They are tasteless, odorless, and colorless, and do not discolor on exposure to relatively high temperatures or sunlight. Electrical properties are excellent, particularly arc resistance.

FORMULA 4

FORMULA 5

The methylol melamine compounds behave somewhat like the methylol ureas when reacted with alcohols under mildly acid conditions, forming alkoxymethyl melamines. The methoxy compounds or methyl ethers, as they are sometimes described, are generally water-soluble, whereas the ethyl and higher alcohol derivatives show decreased solubility in water but are soluble in organic solvents.

Molding compounds

Melamine-formaldehyde condensation products are processed into molding compounds by methods similar to those used in the manufacture of the ureas. As with the latter materials, dyes or pigments may be incorporated to produce opaque or translucent colored material. The moldings are similar in appearance to ureas but possess unusual heat resistance and mar resistance. These latter properties have widely extended the range of their application.

The molding of fine-quality dinnerware is the most successful and spectacular use for alpha cellulose-filled melamine-formaldehyde molding compounds. This application now represents by far the largest single outlet for the melamines. The attractiveness of melamine dinnerware can be enhanced by the use of decorative overlays which are now available in a wide range of colors and designs.

Other important uses for the melamines are in aerosol dispensers, boil-resistant buttons, coffee makers, soda dispensers, flatware, and cutlery handles.

The alpha-filled melamines are available in different degrees of plasticity, but the bulk of the material is sold in a soft plasticity suitable for transfer or plunger molding. All grades are suitable for preheating by high-frequency methods.

Fillers

The properties of melamine molding compounds vary widely according to the kind of filler

that is used in it. For example, wood flour may be used for the production of general-purpose industrial molding compounds for the molding of parts such as auto ignition components, connector plug inserts, and watt-meter blocks. The parts possess high arc resistance and dielectric strength, combined with relatively low specific gravity.

Cotton fabric may be used as a filler for molding material intended for the production of shock-resistant articles such as service trays.

Mineral fillers such as asbestos may be used for molding compounds intended for industrial applications requiring maximum arc- and heat-resistance and dielectric strength. The properties of such parts are maintained up to temperatures that can go as high as 400° F.

Glass fiber-filled material is available for applications requiring a combination of impact strength, high heat resistance, and good electrical properties, including maximum arc resistance.

Laminating

Melamine resins are widely used in laminated products. Sheets of paper, glass cloth, or other fabric are impregnated with the resin solution and dried to a controlled moisture content. Several plies of the impregnated sheets are laminated in a platen press and cured at temperatures of 290 to 320° F. for 15 to 30 min., at pressures ranging from 1000 to 2000 p.s.i. This type of application has enjoyed its greatest success in decorative and durable laminates for tabletops and similar applications.

Adhesives

Certain melamine resins can produce excellent bonds between a variety of surfaces when heat-set. Commercial formulations, however, are usually melamine-fortified urea adhesives. In contrast to urea-formaldehyde adhesives, the available melamine-urea types presently cannot be cold-set.

An unusual property of melamine adhesives or melamine-fortified urea resin adhesives is the stability of the dried adhesive after application to the surface to be glued. The applied adhesive is stable for weeks if kept at room temperature, but it cures very rapidly when heat is applied to it.

Stylish housing for intercommunication set for household use is molded of rugged urea in one piece. (Photo, Barrett Div., Allied Chemical & Dye)

Textile processing

Melamine resins have gained wide acceptance for the treatment of rayon, cotton, wool, and other fabrics to impart properties such as shrink resistance, water and stain repellency, wrinkle resistance, and fire retardance. The melamine resin is usually applied to the goods from a water solution. The goods are dried at a temperature high enough to cure the resin, and finally washed to remove excess accelerator and any of the uncured resin that may remain.

Paper treatment

Melamine-formaldehyde condensation products, particularly those made with the lower formaldehyde/melamine ratios, have found extensive use in improving the properties of paper and imparting wet strength to it. Under certain acidic conditions, methylol melamines can react to give cationic colloids that exhaust quantitatively on the negatively charged paper fiber. The resin is usually added to the slush stock. The resin cures during the drying of the sheet, producing remarkable improvements in the physical properties of the paper. Wet strength is increased severalfold and dry strength improved by the addition of the resin.

Surface coatings

The alkylated methylol melamines, especially the butylated types, are used in combination with alkyd resins for the production of high-quality industrial baking finishes. Their behavior is similar to that of the corresponding urea resins, but the melamines are more effective hardeners for the enamel film. They develop improved mar resistance and increased water and alkali resistance. Initial color is at least equal to that obtained with the ureas and color retention is much better at elevated temperatures. Melamine-resin-fortified alkyd resins have unusual exterior durability.

Melamine is also used for plaster reinforcement, ion exchange resins, and leather tanning.

Cellulosics

RECENT DEVELOPMENTS

A lacquer for coating and decorating cellulose acetate (*Rez-N-Lac A*, Schwartz Chemical Co., Inc.) has a nontoxic resin base, permitting use of the lacquer on children's toys and other objects that come in contact with the body. The lacquer will not flake or craze nor become brittle.

Cellulose acetate film (*S-652*, Celanese Corp. of America) is used by merchants for wrapping food and produce before it is put on the shelf. The acetate stays crisp and breathes, preventing foggy-looking packages. It is furnished in bundles of 1000 units in sizes ranging from 10 by 10 to 20 by 20 in., and can be sealed easily with plates or hand irons with polytetrafluoroethylene-impregnated fibrous glass pads.

A quick-drying lacquer (*Rez-N-Lac B*, Schwartz Chemical Co., Inc.) for coating and decorating butyrate has permanent adhesion and low flammability. The lacquer can be applied by brush or spray. It is nontoxic and waterproof, and does not flake or craze.

Oldest of the synthetic plastics is cellulose nitrate, dating back to the work of Braconnot in France, 1833. Schoenbein, Germany, 1845, and Parkes, England, 1855-65, also experimented with cellulose nitrate; but John Wesley Hyatt, United States, is generally credited with being the first to work successfully with this material as a plastic mass rather than in solution. In 1869 he and his brother took out a patent for making solid collodion (Celluloid) which was the pioneer material for many processes and applications used in the plastics industry.

Meanwhile, in an effort to discover a less flammable material, research conducted by Schützenberger and Cross and Bevan (1894) led toward the development of cellulose acetate plastic. Preparation of a plastic from cellulose acetate was first mentioned in United States patent literature in 1903.[1]

As early as 1912, cellulose acetate found outlet in photographic film. In World War I, it was employed in dopes for airfoil coverings. Later, a process was developed for making cellulose acetate filament which could be woven into fabric.[2] Cellulose acetate sheets, rods, and tubes appeared on the U. S. market in 1927. This was followed by the appearance of cellulose acetate molding powders in 1929.

Research on treatment of cellulose with higher aliphatic acids resulted in a U. S. patent for the manufacture of cellulose acetate butyrate, issued to Clarke and Malm in 1932. The material appeared on the market at that time for use in protective coatings. The molding composition followed in 1938.

Among the cellulose esters, cellulose propionate is the most recent commercial plastic. A patent covering the preparation of cellulose propionate was issued in 1931; but it remained a laboratory plastic until 1945, when a process was developed for economically producing propionic acid from natural gas.

The possibility of using a cellulose ether as an industrially useful product was proposed in 1912 by Leuchs in Germany, Lilienfeld in Austria, and Dreyfus in France. Lilienfeld was granted a U. S. patent[3] in 1917 for use of ethyl cellulose in a plastic composition. In 1935 and 1937, respectively, two of the current manufacturers[4] undertook commercial production of this material.

Other cellulose ethers have also proved commercially useful; among these are methyl cellulose, carboxymethyl cellulose, and hydroxyethyl cellulose.

During the earlier development of cellulose plastics, research was conducted also on the conversion of solid cellulose into liquid chemical compounds, and the subsequent regeneration of the cellulose in the form of films (cellophane) and filaments (rayon).

The cellulosics are prepared by various treatments of carefully purified cotton linters or wood cellulose having a high alpha-cellulose content. The cellulose molecule is composed of as many as 3000 glucosidic units. Each unit provides three hydroxyl groups for esterification. Controlling factors in the preparation of the various cellulose esters and ethers are the condition of the cellulose, the kind and relative amounts of ingredients used, and the time, temperature, and agitation of reaction.

Cellulose nitrate: Cellulose nitrate is prepared by treating properly conditioned cellulose with a mixture of nitric and sulfuric acids. Spent acid is drained off by centrifuging. The nitrated material is given prolonged treatment with boiling water, bleached, washed repeatedly, and subjected to a dehydrating operation by which, under hydraulic pressure, most of the water is replaced by alcohol.

Cellulose acetate: Preparation of cellulose acetate is accomplished by treating cellulose with acetic acid and acetic anhydride in the presence of a catalyst such as sulfuric acid. Cellulose triacetate of about 62.5% combined acetic acid content is formed by the reaction. This is soluble in the treating acids, forming a heavy dope. Water is added to partially hydrolyze or deacetylate the cellulose triacetate. Cellulose acetate is then precipitated in water, washed, and dried.

Cellulose acetate butyrate: To prepare cellulose acetate buty-

[4] Hercules Powder Co., The Dow Chemical Co.

rate, the cellulose is treated with a mixture of acetic and butyric acids and anhydrides, the amount of each ingredient depending upon the properties which it is desirable to have in the final product.

Cellulose propionate: Similarly, the reaction of propionic acid and anhydride on cellulose in the presence of a catalyst yields cellulose propionate.

Ethyl cellulose: Sodium cellulose is produced by the action of a strong alkali, such as sodium hydroxide, on cellulose. This is subsequently acted upon by ethylating agents such as ethyl chloride or sulfate which place the ethyl groups on the cellulose molecule. Ethyl cellulose thus formed is first washed and then purified.

Carboxymethyl cellulose: Carboxymethyl cellulose (cellulose glycolate) is composed of a carboxylic acid bound to the cellulose molecule by an ether linkage. Upon treatment with a fairly strong acid, the sodium salt is converted to the free acid which is insoluble in water. In some cases other salts may be useful; the ammonium salt, on heating, loses ammonia and is thus converted to the free acid; the addition of aluminum, iron, or other heavy metal ions converts the sodium salt to insoluble compounds. The cellulose derivative is precipitated from solution by ferric chloride, ferrous sulfate, stannous chloride, aluminum sulfate, or basic lead acetate. Barium nitrate produces a thixotropic gel.

Hydroxyethyl cellulose: When ethylene oxide is reacted with cellulose, a caustic-soluble hydroxyethyl cellulose is first produced. As additional hydroxyethyl groups are attached, the cellulose derivative becomes more and more water sensitive, until water solubility is reached. Metallic ions, acids, or alkalies cannot be used to precipitate hydroxyethyl cellulose from the aqueous solution.

Regenerated cellulose (cellophane): For the preparation of regenerated cellulose, sheets of sulfite wood are steeped in a carefully controlled solution of sodium hydroxide, resulting in a product known as sodium or alkali cellulose. Excess liquor is removed, and the alkali cellulose sheets are shredded and aged. Treatment with carbon disulfide follows, producing cellulose xanthate. This, in turn, is mixed with dilute sodium hydroxide solution to yield a uniform colloidal suspension, or viscose, which is aged and filtered. Regeneration is accomplished by extruding the viscose, in sheet form, into an acid coagulating bath which reacts with the viscose solution to form cellulose, sodium sulfate, and carbon disulfide.

Cellulose nitrate

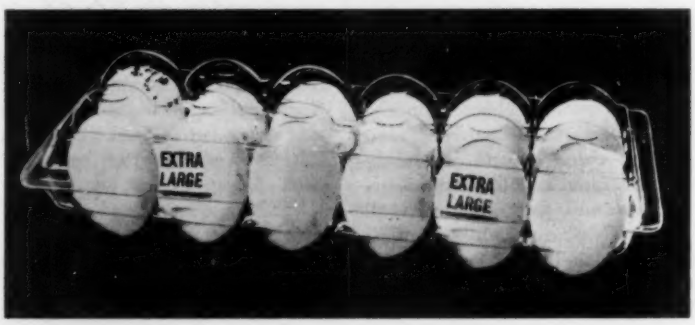
Compounding and processing: Several grades of cellulose nitrate are available, differing in nitrogen content as well as in the degree of viscosity.

Complete esterification provides a nitrogen content of 14.16 percent. Cellulose nitrate used in explosives contains approximately 13%, that employed in lacquers and photographic film about 12%, and that in plastics about 11 percent. Although the chief difference among the various grades is their rate of combustion, solubility as well as compatibility with plasticizers are also variable factors that have to be taken into consideration.

Camphor is the standard plasticizer for cellulose nitrate, although small admixtures of other materials are also used. Alcohol-wet cellulose nitrate is colloided in masticating mixers with the plasticizers and solvents, and strained under hydraulic pressure while in a soft condition. The material can be colored while being worked in the mixer or during the subsequent rolling operation, when some solvent has been evaporated.

Plastic slabs from the rolls can be block-pressed and skived, or the mass containing a suitable proportion of solvent may be wet-extruded into tubes, rods, or sheeting.

General characteristics: Cellulose nitrate is the toughest of all thermoplastics. This quality and ease of fabrication are the chief advantages of the material. Other desirable properties of cellulose nitrate are its dimensional stability, resilience, and low water absorption.



Chief disadvantage of the material is its flammability. Plasticizers containing chlorine and phosphate as fire retardants have been employed, but these tend to reduce the strength of the resulting plastic. Another disadvantage of the material is its tendency to discolor and become brittle under the effects of sunlight.

Cellulose nitrate is not adaptable for compression or injection molding because of its sensitivity to heat. However, it is readily formed into hollow articles by application of air or liquid pressure between heated sheets, expanding them to the shape of a retaining mold. By other methods of fabrication, sheets, rods, and tubes are converted into many items of decorative and functional value, such as personal accessories, toilet articles, and various types of industrial pieces.

Cellulose acetate

Compounding and processing: Cellulose acetate molding compositions are made from cellulose

Egg carton vacuum formed of clear cellulose acetate sheeting allows shoppers to see eggs, is reusable. (Photo, Celanese Corp. of America)

All parts of telephone base, including housing, pushbuttons, and transparent escutcheon, are molded of tough cellulose acetate. (Photo, Hercules Powder)

acetate flake, plasticizers, pigments, and dyes. In the manufacture of cellulose acetate molding and extrusion compounds, the flake is mixed with suitable plasticizers and colorants. Mixing is carried out on heated compounding rolls, in an extruder, or in a Banbury-type mechanical mixer. Processing temperatures are in the 350 to 500° F. range. Plasticizers used are normally simple organic esters, liquids of high boiling point and low vapor pressure, added in amounts of 10 to 70 parts per 100 parts of cellulose acetate. The plasticizer employed is dependent upon the properties desired in the finished composition. After mixing and colloiding, the material is cut into granules or pellets of the desired size and shape for use in injection molding or extrusion.

General characteristics: Cellulose acetate plastics are notable for their outstanding toughness and high impact strength. They are stable at room temperatures, with excellent resistance to discoloration or deterioration induced by sunlight. Materials can be produced over a wide range of rich lustrous colors, including translucents, transparents, and special color effects. Cellulose acetate is a good electrical insulator, and the clear material makes possible a high percentage of transmission of ultra-violet light.

Available in many different types, cellulose acetate is adaptable to a wide application range. The properties of the material are dependent to a large degree on the flow type selected. High-acetyl materials (hard-flow acetates with a combined acetic acid content in the 56 to 58% range) provide increased moisture resistance and, as a result, greater dimensional stability as well as improved dielectric properties. The medium- and soft-flow materials meeting most general-purpose requirements are compositions based on flake of lower acetic acid content ranging downward from 55 percent.

Present-day uses of cellulose acetate have been further broadened by the increasing trend towards formulating for specific end uses. Selection of the proper flake, combined with suitable plasticizers, yields compositions with the characteristics important to specific applications. The important properties that can be "built in" to cellulose acetate include flame resistance, resistance to blushing, improved dimensional stability, reduced plasticizer migration, inertness to other plastics such as acrylics and styrenes, and resistance to specific chemicals, e.g., dichlorobenzene.

Applications: Large-volume markets for cellulose acetate are toys, beads, cutlery handles, knobs, electrical parts, and housings for small-motored electrical appliances. In sheet form, cellulose acetate is widely used as a packaging material, electric insulation, and tape. Vacuum formed sheeting is in growing use in the fabrication of displays, custom-packaging, and small household and personal products.

Newest large-volume application for acetate is ladies' shoe heels. The molded acetate heels are claimed to cost from 2 to 4¢ less than wooden heels with lacquer applied and are characterized by resilience and toughness. Consumption of acetate for heels was estimated at least as high as 500,000 lb. a month by the end of 1956.

Cellulose acetate butyrate

Compounding and processing: Cellulose acetate butyrate requires less plasticizer than does cellulose acetate. In general, the mixed ester has greater solubility in a wider range of solvents and is compatible with a greater number of plasticizers. Pigments and dyes give translucency and color.

Cellulose acetate butyrate plastics are ordinarily shaped by injection molding and continuous extrusion. The material can be injection molded at the highest speeds possible with plastics. Large, intricately shaped articles can be molded in single molds. Compared to cellulose acetate, cellulose acetate butyrate requires less pressure in molding than is indicated by flow designation. To a certain point, flow increases uniformly with temperature, but the material flows considerably faster beyond this critical point. Thus it is possible to obtain grades which, below molding temperature, have relatively high resistance to heat, but flow at molding temperature.

The material is suitable for continuous extrusion under heat and pressure without the use of solvents. Extruded sections can have close tolerances.

General characteristics: The primary physical properties of cellulose acetate butyrate are a horn-like toughness, high impact strength, uniform texture, dimensional stability under normally varying conditions of temperature and humidity, and low moisture absorption. The material is resili-

Colorful portable transistor radio case is molded of rugged cellulose propionate, will not break even if accidentally dropped. (Photo, Celanese Corp.)

ent, light in weight, and has a high surface luster, dielectric strength, and low heat conductivity. It is available in more than 19,000 colors and color effects. Clarity ranges from transparent through translucent to opaque. Variegated, metallic, fluorescent, and pearl effects may be produced.

Like cellulose acetate, cellulose acetate butyrate is easily fabricated and machined with tools used for wood and metal. Molded and extruded pieces can be cemented in a bond as strong as the material itself. Cellulose acetate butyrate is not compatible with cellulose acetate.

Melt-coating compositions of cellulose acetate butyrate are used to produce a brilliant, flexible, waterproof finish on paper and fabric. The same compositions mixed with oil make continuous, tough, transparent coatings, easily cut and stripped, for the protection of metal tools and parts for shipment.

When extruded over rigid metal, cellulose acetate butyrate provides a surface that is tough, chip-proof, and resistant to perspiration, grease, and other contaminants.

An economical and quick method for fastening fabric wall-covering panels in place is also provided by cellulose acetate butyrate strips. These assemblies are employed in airplane interiors, where the light weight of butyrate is an advantage.

Pipe extruded from cellulose acetate butyrate is being used for irrigation, salt water disposal, gas service lines, and as electrical conduit for telephone and power cables.

There is increased interest in extruded sheeting for use as explosion-vent windows, and indoor and outdoor signs made by vacuum forming from heavy-gage sheeting up to 0.125 in. thick.

Cellulose acetate butyrate film is used as primary insulation on solid and stranded wire and cable, permitting an important reduction in wire diameter and saving weight.

Pipe made of cellulose acetate butyrate is used as power cable conduit. Material combines high-impact strength with dielectric strength. (Photo, Eastman)

Cellulose propionate

Compounding and processing: Cellulose propionate requires less than half the plasticizer needed to produce cellulose acetate butyrate plastics of comparable flexural strength. It is compatible with a considerably larger number of plasticizers; compounds can therefore be plasticized and modified to produce moldings of a great variety of properties.

Cellulose propionate is best suited to injection molding and extrusion. It has excellent flow characteristics which provide noncritical molding temperatures over a range of 80° F. Unless inserts, machine limitations, heavy cross-sections, or ribbings are involved, it has a shorter cycle than other cellulosics. In all except the hardest compositions there is no trace of skin or laminations.

General characteristics: Cellulose propionate is an unusually stable cellulose ester, emitting no odor of propionic acid either during molding or in the finished piece. Retention of plasticizer is excellent. Weatherability characteristics are superior to cellulose acetate while being equivalent and, in some instances, superior to other cellulosic molding materials. Although not miscible with cellulose acetate, ethyl cellulose, or resinous plastics such as polystyrene, cellulose propionate is compatible with cellulose acetate butyrate.

Among the cellulosics, cellulose propionate is close to ethyl cellulose in toughness and shock resistance. High shock resistance is maintained without sacrifice of other desirable characteristics. Articles produced from cellulose propionate can be printed and lacquered without fear of tackiness. Weld lines are almost unnoticeable, and weld strength is high as indicated by both impact and tensile strength tests. Surface finish of injection molded pieces is brilliant and so lustrous and free from smudges that many parts require no buffing or similar finishing operation.

Applications: Current markets for cellulose propionate are automotive parts, pens and pencils, telephone housings, ladies' shoe heels, toys, radio and television parts, toothbrushes, and sunglass frames. Special formulations are also available for potable water applications.

Ethyl cellulose

Compounding and processing: The purified white granular ethyl cellulose is mixed with plasticizers and colored to give molding material. Many modifiers are available for ethyl cellulose formulations.

On standard compression molding equipment, temperatures in the range of 350 to 380° F. are required, and pressures of 2000 to 4000 p.s.i. Injection molding temperatures of 375 to 430° F. with

pressures of 8000 to 20,000 p.s.i. are common practice. Extrusion by the dry method can be accomplished at temperatures approximating those of injection molding. Casting hollow articles of ethyl cellulose is readily accomplished.

Sheets can be drawn or swaged. Thicknesses up to 0.125 in. have been fabricated by drawing. Machining can be done with the same equipment used for other cellulosics or for wood.

Lacquers can be formulated for brushing, spraying or dipping, and formulas are available for hot-melt coating of paper and cloth.

General characteristics: A number of different grades of ethyl cellulose are commercially available. The more completely ethylated product, 48 to 49.5%, has better compatibility with waxes, resins, and other modifiers. Generally, this type of ethyl cellulose product has good water resistance, wide solubility, and a lower softening point than the lower ethylated products. The ethyl cellulose with an ethoxyl content of 46 to 48% gives a tough material with excellent low-temperature characteristics. The viscosity of the ethyl cellulose flake also can be varied and, in general, the higher the value the greater the strength and toughness of the end product.

The low water absorption and chemical stability of ethyl cellulose have resulted in compositions possessing excellent dimensional stability over a wide range of temperatures and humidities. High-impact strength at normal and sub-zero temperatures is characteristic of ethyl cellulose. Electrically, ethyl cellulose is usually superior to other cellulose derivatives.

Ethyl cellulose is the lightest of the cellulose products now on the market. With a density of 1.07 to 1.18, it has great value in those applications in which the factor of weight is important.

In addition to plasticizers and solvents, many compounds in the field of esters, natural resins, resin acids, resin esters, tars, and waxes can be used with ethyl cellulose. It is also compatible with cellulose nitrate, but not with cellulose acetate nor with butyrate.

Advantage is taken of the strength characteristics, moisture resistance, and dimensional stability of ethyl cellulose in the production of items which must inevitably be subjected to abuse. Ethyl cellulose is useful in a chemical-resistant insulating and waterproofing material which can be employed as a sealing or potting compound with high resistance to electric current.

Cast ethyl cellulose dies and jigs have provided a quick and relatively inexpensive means to meet tooling demands. The casting compound retains its toughness, dimensional stability, and other properties under varying conditions of application. The product can be reused without processing.

Flexible films of ethyl cellulose are serviceable as moisture barriers. As strip coatings, they provide an easy method of preventing corrosion and damage on metal parts in transit or in storage.

Outdoor sign, 25 by 40 ft., is made of corrugated sheet (see close-up), extruded of weather-resistant cellulose acetate butyrate. Continuous extrusions 40 ft. long eliminated problem of assembling smaller units. All decorating on the sign face is done by overlay butyrate sheet in various colors. (Photo, Eastman Chemical)

Carboxymethyl cellulose

Compounding and processing: This cellulose derivative is compatible in varying proportions with many water-soluble plasticizers, natural gums, and other film formers. Highly viscous, stable aqueous solutions can be obtained which, upon evaporation, leave colorless, tough, transparent films that are unaffected by most organic solvents, oils, and greases.

General characteristics: Carboxymethyl cellulose is available in three viscosity types: low, medium, and high. These products can be rapidly dissolved in water-ethanol mixtures, when the alcohol does not exceed 50% of the mixture. Films cast from sodium carboxymethyl cellulose solutions and painted with solutions of

aluminum sulfate, barium nitrate, stannous chloride, basic lead acetate, ferric chloride, or ferrous sulfate are insoluble in water. The solutions of sodium carboxymethyl cellulose are commonly utilized for their thickening properties as viscosity control agents in the preparation of latex emulsions, as emulsifying agents in the preparation of oil-in-water solutions, and as bases for ointments, boiler compounds, oil-drilling muds, and insecticides. Other applications for this cellulose derivative are as coatings for carton board used in the manufacture of containers which must be greaseproof.

Hydroxyethyl cellulose

As well as resembling other commercial cellulose derivatives, hydroxyethyl cellulose, in many respects, resembles the water-soluble or water-dispersible alginates, natural gums, and starches. Some advantages it exhibits over these materials are uniformity, complete solubility in water at all temperatures, and stability of solutions. A low-viscosity solution of hydroxyethyl cellulose is comparable in consistency to gum arabic.

Hydroxyethyl cellulose *dry powder* is a free-flowing white to light tan powder available in several types that yield solutions of different viscosities. In the dry form it can be esterified or etherified more easily than cellulose. Dry hydroxyethyl cellulose does not melt but decomposes gradually at temperatures above 300° F., especially in the presence of acids, alkalies, or salts, behaving in this respect much like other cellulose materials such as paper or cotton. It begins to char at about 400° F., while long exposure at slightly lower temperatures, especially in the presence of acidic materials, causes browning or embrittling. The powdered material retains its hygroscopicity after application and remains free-flowing even when it contains 25% water.

Hydroxyethyl cellulose *aqueous solutions*, in general, are insoluble in most organic solvents. They are compatible with gelatin, gum arabic, gum tragacanth, British gum, and other water-soluble film-forming materials. Mineral acids hydrolyze hydroxyethyl cellulose, while strong alkalies cause an initial decrease in the viscosity.

Molded women's shoe heels represent large-volume market for cellulose acetate. Resilient, tough, and low in cost, heels can be used plain or covered. (Photo, Celanese)

On drying, a hydroxyethyl cellulose solution deposits a clear, cellophane-like film that is colorless, odorless, tasteless, soluble in water, and stable to heat and light. The flexibility of these films is greatly increased by adding one of several polyhydric alcohols such as triethylene glycol, a polyethylene glycol, a polypropylene glycol, or glycerol. The films are rendered resistant to water by the addition of glyoxal to the solution, or by reacting the hydroxyethyl cellulose with urea and formaldehyde.

Cellophane

Compounding and processing: The film, prepared by regeneration of cellulose from viscose solution, is immersed in successive purification baths, and finally in dilute solutions of glycerol or other softening agents which may also flameproof the film. The film is then dried to the desired moisture content and sheeted or slit into small rolls. If moistureproof film is desired, a coating composition is applied in very thin layers on both sides of the cellophane.

General characteristics: Commercially, cellophane is the most widely available and least expensive film. It is easily fabricated, and especially adaptable to high-speed automatic machinery and to various printing techniques. Cellophane is suitable for a great many decorative purposes.

Electrical properties of the material permit its use in industrial electrical equipment. The film serves not only as insulation but also as a protection against oil and grease. It is employed in low-pressure molding of laminates to prevent the material from sticking to the mold, and sometimes as the agent upon which plastics are cast.

By itself or laminated to itself, to metal foils, or to various types of paper, cellophane affords excellent protection for fresh and frozen foods, tobacco, textiles, and medical supplies, as well as for metal items.

Cold Molded Organic Plastics

Cold molded plastics were introduced in the United States near the beginning of this century by Emile Hemming. They differ basically from the more common plastics molding materials in that they must be baked after removal from the mold to oxidize and polymerize the binder materials. Cold molded plastics fall into two main categories based on the types of binders employed—organic, and inorganic or refractory. The organic materials are divided into two types—bituminous (asphaltic, binder) and synthetic resin (phenolic binder). Inorganic cold molded materials are discussed in the chapter on Inorganic Plastics. Asbestos is a common filler for all types and the high-heat resistance characteristic of these materials is due to the asbestos in the formula.

High heat and chemical resistance and low cost dictate choice of cold molded plastics for air contactor arc chutes (above) and control housing (below). (Photos, Rostone)

Bituminous binder: This binder is composed of asphalt, gilsonite, stearine pitch, or vegetable pitch blended with oils, such as linseed, castor, and tung, to form a varnish-like resin. This resin is reduced to proper viscosity with solvents, mixed with asbestos fiber, seasoned, ground, and finally screened.

Phenolic binder: Phenolic resin is treated with a solvent to produce a solution of the proper viscosity; then it is mixed with asbestos fiber, seasoned, ground, and screened to proper size.

Since the cold molded plastics can be squeezed into shape by pressure alone, production is rapid—as high as 3500 to 4000 pieces/hour with certain types of equipment. Baking, required to set the piece after shaping, can be accomplished for a large number of pieces simultaneously, and usually consumes one to several days depending upon the size and cross-section of the piece. On small thin pieces the baking cycle may be considerably under 24 hr.; heavier cross-sections may require up to 72 hours. When organic binders are used, the temperature starts at approximately 175° F. and is raised in hourly increments of 10 to 20 degrees to approximately 450° F.

Ease of fabrication varies according to the type and percentage of abrasive components. Mold wear is also affected by abrasive content. In general, cold molded articles tolerate metal inserts.

General characteristics: Cold molded articles usually lack the surface smoothness, gloss, and appearance that characterize hot molded items. Dimensional differences are relatively large. Through modification of compounds and advances in processing, strides have been successfully made in stabilizing and improving these characteristics.

With some of the newer types of compounds, dimensional variation and design limitations are not so critical. Tensile strength has been improved. Baking is not necessary unless increased tensile strength is essential, or accelerated setting is desired. Color range has been greatly broadened. Mold wear has been reduced. New free-flowing powders are adaptable to rotary presses, and small pieces can be pressed up to 300/minute.

Phenolic compositions surpass bituminous types in both mechanical and electrical properties, and can be made with a finish that is at least comparable to that obtained in hot molding. Both types exhibit resistance to high heat and most alkalies and solvents, and are nontoxic and relatively low in cost. Most of these compositions are molded on hydraulic presses supplied with oil pressure ranging from 2000 to 4000 p.s.i. The somewhat soft pieces are seasoned on perforated trays at room temperature before baking.

Applications: Cold molded organic plastics find applications in many electrical products, such as connector plugs, switch bases, attachment plugs and caps, sockets, outlet covers, and others.

Coumarone-Indene, Petroleum, and Polyterpene Resins

BY P. O. POWERS*

RECENT DEVELOPMENTS

A new series of styrene copolymers have been introduced (*Piccoflex 100, 105,* and *115,* Pennsylvania Industrial Chemical Corp.). The 115 variety is available in flaked form; the other two are available in solid form. These resins have been used in coatings, particularly where excellent water and solvent resistance is required. They are especially adaptable to use in floor coverings, particularly asphalt-filled tile formulations. When properly compounded they can be used for making tile possessing excellent color and color stability, resistance to kerosene and vegetable oils, and good flexibility.

Several new hydrocarbon resin emulsions of petroleum resin have been recently offered (*Piccopale Emulsion A-22, XA-43, N-3,* and *XC-1,* Pennsylvania Industrial Chemical Corp.). A-22 is especially recommended for use with polyvinyl acetate emulsions where it improves adhesion and scrubbability. The XA-43 is particularly recommended for use in paper sizing. The N-3 is a new nonionic emulsion, with excellent stability and unusual resistance to shear. The XC-1 is a new cationic emulsion and on drying exhibits extremely good water resistance characteristics.

An improved terpene polymer (*Piccolyte S115-L,* Pennsylvania Industrial Chemical Corp.) has notably improved color over the usual varieties of terpene polymers; the color is Gardner 2 or better.

Coumarone-indene resins are derived principally from indene; other resins usually classed with coumarone-indene are derived from styrene, cyclopentadiene and their homologs, and other unsaturates.

These resins are being offered in a wide variety of forms from soft resins to hard brittle resins of 140° C. softening point as determined by the A.S.T.M. E-28, ball-and-ring softening point method. The color of the resins also varies widely—from pale resins of less than Coal Tar Color 1, to resins that are dark brown in color. Heavy aromatic oils that find application as plasticizers and as plasticizer extenders are also produced.

The iodine value of the resins may range from practically 0 to over 200, depending upon the starting materials and methods of manufacture. The iodine value does not measure unsaturation quantitatively but indicates reactivity with oxygen.

Finally, the coumarone-indene resins vary considerably in solubility; most of them, however, are soluble in aliphatic solvents, such as mineral spirits. Some of the higher melting varieties require 10 to 30% of aromatic hydrocarbons in the solvent. Certain polymers are soluble in acetone.

The polystyrene resins are rather lower in molecular weight than the polystyrene materials used in the molding field. They are thermoplastic and offer a variety of melting points ranging from 25 to 150° C. These resins are available in flaked, bead, or solid forms. They are soluble in aromatic hydrocarbons as well as in the aromatic petroleum naphthas.

The resins are produced by treating the unsaturated streams with an acid catalyst. The type of catalyst, the temperature of reaction, and the concentration of the reactants determine the type of resin produced. Often the different streams are blended together to reproduce resins of the desired characteristic. After the catalyst has been removed, the solution of resin is dried by evaporation, either with steam or in vacuum or by a combination of both.

Coumarone-indene resins are widely used in coatings, particularly in aluminum vehicles, a field in which their nonpolar character is essential. Coumarone-indene resins are also widely used with drying oils in preparing varnishes of many types. They are occassionally used in conjunction with other resins in preparing varnishes. The resins, in general, have little reactivity with the drying oils, although some types are more soluble after heating with the oil. Part of this effect, however, may be due to depolymerization of the resin. The coumarone-indene type resins do add considerable water resistance and alkali resistance to vehicles in which they have been incorporated.

Concrete sealers, flat wall paints, and wall primers are typical uses, as is membrane curing of concrete.

Asphalt tile continues to be one

* Pennsylvania Industrial Chemical Corp., 120 State St., Clairton, Pa.

Recent Developments and References were prepared by the editors.

of the large outlets for the coal tar hydrocarbon resins. A decade ago these resins were the principal resins used, but the large increase in volume in this field has necessitated the use of other types of resins, particularly petroleum resins. Unlike coumarone-indene resins, however, which can be used as the single resin constituent in tile manufacture, petroleum resins require reinforcement with polystyrene or other more reactive materials. In recent years, polystyrene scrap has been widely used with the petroleum resins for this purpose; coal tar hydrocarbon resins also may be used.

Coumarone-indene resins find a major outlet as aids for softening and processing, and also as reinforcing resins with natural and synthetic rubber. The softer grades are used with the oil-resistant synthetic rubbers as softeners and tackifiers. The harder grades have been found to produce a resin-reinforcing effect, particularly with the butadiene-styrene synthetic rubber.

Petroleum resins

The production of petroleum resins has increased rapidly in the last decade as the supply of coal tar crudes remained relatively stationary, and new types have been added periodically.

The first petroleum hydrocarbon resins offered were rather dark in color and highly unsaturated. However, with improvements in manufacturing methods, a wide range of petroleum resins have now been made available with good color and good stability to aging. The differences between petroleum and coal tar hydrocarbon resins are also tending to disappear and the aromatic content of some petroleum resins is already quite high. Light-colored petroleum resins are soluble in mineral spirits in all proportions. Resins are available in solid and flaked form at melting points of 100° C. and higher. Petroleum resin emulsions of good color are available in all types of emulsion form, both of the anionic and nonionic types, adapted for use in coatings and paper size, and for other industrial applications. Petroleum resins vary somewhat in iodine value and some possess quite high iodine values. Some unsaturated resins absorb oxygen readily, but where this property is undesirable, antioxidants will prevent this change occurring.

In the mastic tile field, petroleum resins are largely used but usually require some higher-molecular-weight material such as polystyrene to reinforce them. Plasticizers from the petroleum field are also used with the resins. Coal tar resins are sometimes used with the petroleum resins in mastic tile manufacture.

Petroleum resins are widely used in rubber compounding. The softer resins are used as plasticizers, while the harder resins are used to impart stiffness to synthetic rubbers. A notable improvement in tensile strength and cut growth is accomplished by the incorporation of such resins in the formulation.

Pale petroleum resins can be used with the drying oils to produce water-resistant varnishes. Gloss and adhesion are also improved by their use. Color stability of petroleum resins is considerably better than that of the coal tar resins. Petroleum resins find extensive applications in adhesives and saturates. They are also widely used to modify other resins. Petroleum resins are readily soluble in paraffinic and chlorinated hydrocarbons but are generally insoluble in the lower alcohols or ketones.

The use of petroleum resins as a saturant for corrugated boxes and as a paper size is being extended, as is the use of these resins in fiberboards.

Terpene resins

Polyterpene resins are firmly established in the adhesives and coatings fields, and wherever a readily soluble hard resin of good color is required. In the last year the polyterpene resins have been in rather short supply due to the greatly increased demand.

Commercial polyterpene resins are lower in density than the coal tar or most petroleum resins. Recent improvements in manufacturing methods have resulted in better and lighter-colored resins. Grades melting from 10 to 135° C. ball-and-ring are produced. The harder varieties are available in flake form. They are composed in their entirety of hydrocarbon.

The terpene resins are used with drying oils in varnishes. Such varnishes made with tung oil have exceptional heat resistance. The vehicles containing terpene resins are characterized by their generally good color retention properties.

Polyterpene resins are compatible with many waxes and may be used in emulsion waxes. They are compatible with polybutenes, chlorinated and cyclized rubbers, and long-oil alkyds. They are used in concrete curing compounds where a pale solution is required. Since polyterpenes blend readily with natural and synthetic rubbers, they are used in rubber compounding and are widely employed in adhesives. Since these resins are nontoxic, they can be employed in food packaging. They are popular in pressure-sensitive adhesives where the properties of tack, light color, and stability are of decided advantage.

Epoxy Resins

BY GEORGE EPSTEIN*

Epoxy resins represent a relatively new and intriguing class of synthetic resins which have found wide application in reinforced plastics, adhesives, coatings, castings, etc.

The epoxy resins are known under a wide variety of designations. The terms epoxy, epoxide, ethoxy, ethoxyline, and oxirane are derived from the fact that these resins are characterized by the  functional group, which may be so termed. The designation "epichlor(o)hydrin resins" results from the fact that epichlorohydrin, a liquid chemical, is generally employed as one of the starting materials in the manufacture of the resins.

Historical development

In 1863 the German chemist A. Wurtz prepared ethylene oxide, and then studied some of its reactions. During the next 80 years various chemists, notably Lindeman, Staudinger, and Schlack, learned how to prepare polymeric resinous materials based on Wurtz's earlier studies. The development of manufacturing and processing techniques was undertaken during World War II and in subsequent years by a number of leading materials suppliers and other interested companies.

From practically zero output prior to 1950, the manufacture and consumption of epoxy resins was reported to have reached almost 30 million lb. in 1954, and was estimated at about 90 million lb. in 1956.

Resin synthesis

The commercial synthesis or manufacture of epoxy resins largely depends upon the reactivity of the oxirane ring  with compounds containing hydroxyl groups (—OH). Epichlorohydrin, in particular, is used in conjunction with various bi- or polyhydroxyl compounds. This chemical is a colorless liquid, boiling at 116°C., and has the chemical structure shown in Fig. 1, below.

Reactions can occur through both the oxirane ring (epoxy group) and the chlorine atom. Use is made of this extensive reactivity both in the preparation of the epoxy resins and in the subsequent curing or hardening of the resins. Reactions can occur with sources of active hydrogen (—H), such as amines, acids, and acid anhydrides, and with compounds containing the hydroxyl (—OH) functional group, such as alcohols and phenols.

The reaction of epichlorohydrin with bi-functional hydroxyl-containing compounds (i.e., with two —OH groups per molecule) is the basis for the manufacture of the commercial epoxy resins. Bisphenol-A (see Fig. 2, right, for chemical structure) is of particular interest because of its symmetrical structure and because it is the most economical dihydric phenol produced in large volume and in relatively pure form. It is a solid with a melting point of 153° C. Glycerol, resorcinol, cresol, various glycols, catechol, hydroquinone, polyhydroxy naphthalenes, novolak-type phenolic resins, and other phenol derivatives are among the many other hydroxyl compounds which may be employed. Some commercial resins are prepared with glycerol and resorcinol, but at present the most important types of commercial resins are based on bisphenol-A.

Chlorohydrins other than epichlorohydrin, such as glycerol dichlorohydrin

($ClCH_2CHOHCH_2Cl$),

can be employed.

Novolak resins (prepared by reacting excess phenol with formaldehyde), treated with epoxylating agents such as epichlorohydrin, can result in resins containing appreciably more reactive epoxy groups per molecule than the standard commercial products. (Diepoxides have a theoretical maximum of two epoxy groups per molecule.) Such resinous products have a greater degree of reactivity, and hence are capable of producing higher heat-distortion temperatures.

Epoxidation of unsaturated (C=C) organic materials offers an attractive means for manufacture of a variety of epoxy resins. Hydrogen peroxide and organic peracids, e.g., peracetic, perbenzoic, and perphthalic acids, are capable of converting unsaturated groups to epoxy (see Fig. 3, below). A diepoxide synthesized by this process was recently announced. Heat-distortion temperatures greater than 450° F. were reported when this resin was cured at 320°F for 6 hr. with HET anhydride and a small quantity of base catalyst.

General properties

The viscous liquid epoxy resins are employed most commonly in casting, potting, laminating, and adhesive-bonding applications. The solid grades are used generally for coatings, and in some cases for laminating and adhesive-bonding applications.

The resins described above are thermoplastic long-chain (essentially linear) pre-polymers (see

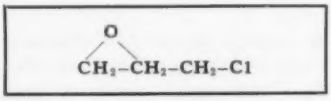

Fig. 1

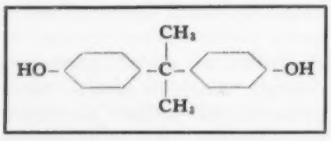

Fig. 2

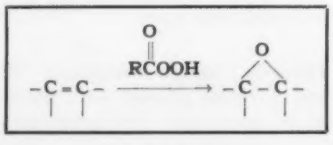

Fig. 3

A self-hardening plastic-metal compound (*Formex No. 77*, Travaco Laboratories) has half the density of equivalent compounds and a controlled pot life of from 3 to 90 minutes. When mixed with the catalyst supplied, it hardens like granite in minutes, forming a permanent bond with plastics, metals, wood, ceramics, and concrete.

Epoxy resins for primary electrical insulation are now available in tape form (Minnesota Mining & Mfg. Co.). The tapes, in fibrous glass cloth form (*X-1035*) and in a nonwoven fibrous polyester mat form (*X-1045*), are impregnated with uncured epoxy resin. After oven cure, the resin sets into a hard, homogeneous mass around the protected unit providing mechanical support and a moisture barrier. The tapes are designed to meet Class B electrical insulation performance requirements.

A clear, pale, low-viscosity epoxy resin (*Epi-Rez 507*, Jones-Dabney Co.) has been developed to fill the growing need for flexible epoxy compositions. Cured resins range from tough, flexible products to hard, high-impact resistant materials. The mixture has a long pot life and cures with a very low exotherm. By the use of an accelerator, it is possible to obtain a wide range of stability and speed of cure.

A curing agent (4,4′-diaminodiphenylsulfone, Merck & Co., Inc.) for epoxy resins is said to improve the high-temperature performance and electrical characteristics of the cured resins.

A protective cream (*Kerodex*, Ayerst Labs.) is useful as a deterrent of contact dermatitis among workers who handle epoxy resins, glass fibers, etc. It is available in both water-repellent and water-soluble types.

Bonding agents consisting of epoxy resins alloyed with metal and nonmetal reinforcements (*Resiweld Plastic Alloys*, H. B. Fuller Co.) are said to give permanent and impact-resistant bonding to practically all plastics, metals, wood, glass, concrete, and other surfaces.

An epoxy resin wrinkleproofs white cottons, gives them a "wash-and-wear" finish, and prevents discoloration (*Eponite*, Shell Chemical Corp.). The resin permits washing, bleaching, and ironing of white goods without yellowing or loss of strength.

An epoxy compound (*Flawmaster*, Carl H. Biggs Co., Inc.) is described as a metal putty useful for filling blowholes of various sizes in both machined and raw castings. It is supplied in a kit, as a three-component compound consisting of resin, hardener, and a supply of very finely pulverized blended powder. It can be cured at room temperature.

A high heat-resistant epoxy resin formulation, with a heat distortion temperature of 600° F., can be mixed at room temperature and has a cure cycle of 6 to 8 hr. at 300° F. One version of this material (*Epoxylite No. 811-9*, Epoxylite Corp.) can be used to prepare molded coil insulation for large electric motors. A second version (*Epoxylite No. 813-9*) is suitable for potting all varieties of electrical apparatus. A third version (*Epoxylite No. 812-9*) is recommended as an extremely versatile heat-curing adhesive.

An epoxy hardener (*No. 888*, Marblette Corp.) makes possible epoxy castings and laminates with a heat resistance between 600 and 700° F., according to the manufacturer.

New transparent, flexible, and foam encapsulating compounds (Telectro Industries Corp.) are available for industrial and commercial applications. The transparent compound sets in 15 min., is inexpensive, consists of only two components, and is easily released from the molds. The flexible compound is an epoxy formulation featuring variable flexibility and is less expensive than other epoxy formulations. The foam compounds are available in various densities and require low temperatures to 150° F. for curing.

An inexpensive room temperature-curing epoxy resin (*Maraset No. 616*, Marblette Corp.) has been used to make bulk-mass application castings to 300 pounds.

A low-viscosity hardener (*Sonite No. 23*, Smooth-On Mfg. Co.), for use with an epoxy resin casting compound (*Sonite XI*) used in potting and encapsulation, imparts flame, mechanical, and thermal shock resistance.

The hardness of a new lead-epoxy compound (*Leadcast*, Telectro Industries Corp.) can be controlled from that of a rubberlike material to that of cast aluminum. Applications are primarily in the field of radiation shielding in source containers, instrument housings, interlocking bricks for temporary or removable shielding, and the like.

A two-component epoxide casting resin (*Stycast 2741*, Emerson & Cuming, Inc.) imparts controlled flexibility to the finished product. It retains flexibility at −70° F. and is recommended for encapsulating, potting, and sealing applications requiring low-temperature use. It can also be used at 300° F. without harmful effects.

For patching and protecting eroded concrete, epoxy resins (*Epocast* resins, Furane Plastics, Inc.) are available. Various formulations are required to fill the cracks, apply fillets to corners, and coat the entire area for protection.

Epoxy-tar protective coatings (*Carbomastic*, Carboline Co.), for use in general maintenance, equipment exteriors, tank linings, and floors, have a solids content ranging from 85 to 90 percent.

Fig. 4, below). As such, they are soluble in a wide variety of solvents. Ketones, esters, alcohol-ethers, and chlorinated hydrocarbons are particularly effective, the solubility of the resins decreasing as molecular weight and softening point increase. Alcohols and aromatic hydrocarbons are not active solvents for the solid grades. The liquid resins are quite soluble in aromatics, e.g., benzene, toluene, and xylene, but not in alcohols. Alcohol-aromatic hydrocarbon solvent combinations may be employed in conjunction with solid resins for coatings.

The end groups of these resins are extremely reactive epoxy groups and, for n = 1 or greater, the chain contains secondary alcohol (—OH) groups which are also reactive under certain conditions. The molecular chain consists only of C—C and ether linkages, which account largely for the excellent chemical resistance and stability of the resin when fully cured, as compared with the polyesters. The wide spacing between the functional epoxy and hydroxyl groups assists in providing inherent flexibility. The highly polar groupings contained by the molecule provide the excellent adhesion to metals and to a wide variety of other surfaces which are polar and/or polarizable in nature. The etherification of the phenolic OH group accounts for the good color retention and alkali resistance of the epoxies. Due to the large variety of chemical groupings included within the molecular chain structure (alkyl, aryl, etc.) the epoxy resin tends to be compatible with a variety of other resins and elastomers, e.g., phenol-formaldehydes, urea-formaldehydes, polyvinyls, and polysulfide and nitrile rubbers.

The presence of epoxy and hydroxyl groups in the uncured resin results in high intermolecular association. Hence, during cure, changes in volume are quite small (i.e., there is very little shrinkage) and associated strains are minimized. The fact that no volatiles are given off during cure is, of course, another significant factor in minimizing shrinkage.

Impurities not removed from the resinous product (e.g., uncombined reactants, phenol, caustic, salt) will impair the physical and mechanical properties of the final material. There is also a tendency toward inhibition of cure when amine curatives are involved. It is for these reasons that thorough washing is the practice in the manufacture of epoxy resins.

Curing

The cross-linking and coupling processes involved in transforming the thermoplastic epoxy resins into hard, rigid, thermoset solids are designated as curing. "Hardening," "converting," and "setting" are alternative designations describing this chemical transformation, whereby physical and chemical properties are altered in the direction of increased strength, hardness, rigidity, etc.

The mechanisms by which epoxy resins are cured are dependent upon the nature of the curatives employed. Two types of materials generally are used: 1) amines and 2) acids (anhydrides).

In general, epoxy resins cured with amines have shorter pot lives or working times, shorter curing cycles, and higher exotherms, i.e., considerable heat may be evolved during the curing reaction. Curing at room temperature or only moderately elevated temperatures (e.g., 200°F.) is frequently possible. Anhydride-cured resins, on the other hand, usually have longer pot lives, longer curing cycles, and appreciably lower exotherms. Moderate to high temperatures (300 to 500°F.) usually are required for curing. Higher concentrations of anhydride curatives are necessary for effective curing. This is usually an advantage for handling purposes. Representative commercial curing agents are listed in Table I, p. 108.

Surface coatings

Epoxy resins have found widespread use in surface coatings due to their excellent adhesion, durability, and chemical resistance. There are three major families of epoxy-base surface coatings: 1) epoxy-phenolic and epoxy-urea; 2) epoxy-esters; and 3) epoxy-polyamines.

Epoxy-phenolic and epoxy-urea: High-molecular-weight epoxy resins are heat-cured with urea, melamine, or phenolic resins to form coatings with maximum hardness and chemical resistance to acids, alkalies, and solvents. Reaction of the epoxy occurs through the methylol groups ($-CH_2OH$). Phenolic modifications have poorer color and require higher baking temperatures (350°F.) than urea-formaldehyde resins; however, they have greater chemical resistance. Aromatic or ketone solvents usually are used for thinning these blends, with a solids content of 35 to 40% for spraying.

Epoxy - phenol - formaldehyde coatings are outstanding in applications requiring maximum chemical resistance and toughness, such as drum linings, wire enamels, coatings for food containers and collapsible tubes, and protective coatings for metal furniture, pipes, tanks, tank cars, ducts, etc. Epoxy-urea-formaldehyde coatings tend to be somewhat more flexible and are used in similar applications. They have excellent color retention and produce superior white baking finishes.

Epoxy-esters: Fatty acids may be incorporated with epoxy resins by esterification to low acid values, under inert gas at temperatures of about 500° F. Drying-oil fatty acids generally are

(Note: Furane also carries curatives of Ciba Co.)		
General Mills Inc., Chemical Div.		
Versamid 100 and 115	Polyamides	Non-toxic; extremely viscous liquid; low-exotherm; improved flexibility and impact resistance; room-temperature curing possible; LTS
Versamid 125	Polyamide	Non-toxic; viscous liquid, more fluid than Versamid 115; low exotherms; improved impact resistance; room-temperature curing possible; LTS
Hastings Plastics, Inc.		
Hapex 1201	Aliphatic amine	Short pot life; room-temperature curing; LTS
Hapex 1221	Aliphatic amine	Moderate pot life; room-temperature curing possible; LTS
Hapex 1210	Modified aromatic amine	Long pot life; low-viscosity liquid; high-temperature curing (to 300° F.); HTS

See Footnotes on opposite page.

used. Film properties are not equal to those of epoxy-phenolic resins, but have better performance qualities than standard alkyd baking enamels. Epoxy-esters may be baked or air-dried through the addition of driers, especially cobalt naphthenate.

Styrenated esters (containing styrene in addition to the epoxy-fatty acid ester) are faster-drying, and have good weathering and alkali resistance. Rosin esters are prepared by esterifying the epoxy resin with rosin, and then dispersing the resulting product in a drying oil by heating at about 550°F.

Epoxy-esters are readily pigmented to yield high-gloss finishes, capable of rapid drying, high abrasion, and mar resistance, as well as excellent adhesion, durability, and chemical resistance. Applications include spar varnishes, printing inks, cement paints, metal primers, coatings for food containers, tools, and various items of hardware, and protective coatings for use in chemical plants.

Epoxy-polyamines: A third family of coatings results when epoxy resins are cross-linked with polyamines. For surface coatings, the epoxy resin is put into solution, and the amine catalyst added just before use. The pot life and curing conditions of the catalyzed resin depend upon the specific polyamine used, and the solvent system and amount thereof. A few percent of urea-formaldehyde resin frequently is included in order to improve the surface leveling characteristics.

Polyamides give greater flexibility, but less chemical resistance than polyamines. They have been used as coatings for paper and cardboard.

Epoxy-Thiokol polysulfide mixtures, cured with amines, provide a range of flexibility. Such systems are used for protection of strain gages and for low-permeability liners in pressure vessels.

Clear or pigmented amine-cured epoxy coatings are also obtainable with outstanding chemical resistance. They are being employed in chemical plants and

TABLE I: Representative commercial curatives for epoxy resins (Continued from opp. page)

Source	Chemical type	Characteristics and usage[1]
Jones-Dabney Co.		
Epi-Cure 82	Aliphatic amine adduct	Short pot life; rapid curing at room temperature possible; high exotherms; LTS
Epi-Cure 83	Modified aliphatic amine	Long pot life; moderate-temperature curing (to 200°F); low exotherms; LTS
(Note: Mixtures of Epi-Cure 82 and 83 are recommended for controlled reactivity.)		
Epi-Cure 84	Aromatic amine mixture	Long pot life; low-viscosity liquid; high-temperature curing (to 300°F); postcure (400°F) for optimum properties; HTS
Epi-Cure 85	Aliphatic amine adduct	Short pot life; room-temperature curing; used with Epi-Cure 82 to adjust flexibility; LTS
Marblette Corp.		
No. 661, No. 665, and No. 680	Aliphatic amines	LTS
No. 900 and No. 903	Aromatic amines	HTS
No. 888	Acid anhydride	HTS
Naugatuck Chemical Div., U.S. Rubber Co.		
TONOX-PL	Modified aromatic amine (methylene dianiline)	Long pot life; solid, generally melted for ease of mixing; HTS
Rohm and Haas Co.		
DMP-10	Dimethylaminomethylphenol	Low-temperature curing; LTS
DMP-30	Tri(dimethylaminomethyl)phenol	Low-temperature curing; LTS
Shell Chemical Corp.		
Curing Agent A	Diethylaminopropylamine	Short pot life; liquids, somewhat volatile; room-temperature curing possible; LTS
Curing Agent CL	Metaphenylenediamine	Long pot life; solid, requires melting for use; high-temperature curing (to 300°F); postcure (400°F) for optimum properties; HTS
Epon Curing Agent Z	Aromatic amine mixture	Long pot life; low-viscosity liquid; high-temperature curing (300°F); HTS
Epon Curing Agent D	2-Ethyl hexoic acid salt of DMP-30	Moderate pot life; moderate-temperature curing (to 250°F); excellent for castings; LTS
Curing Agent DDS	Diaminodiphenylsulfone (DDS)	Long pot life; solid powder, requires heating or dissolving for mixing; requires high-temperature curing and postcures (to 400°F); HTS
Epon Curing Agent BF_3-400	Boron trifluoride-monoethylamine complex	Very long pot life; high-temperature curing (200-450°F); LTS; recommended with DDS to accelerate cure.
Epon Curing Agent T	Aliphatic polyamine	Non-toxic; short pot life; room-temperature curing possible; recommended for automobile body patching and tooling; LTS
Epon Curing Agent U	Modified polyamine adduct	Short pot life; easily handled; moderate-temperature curing (to 200°F); LTS
Smooth-On Mfg. Co.		
"Sonite" No. 01	Aliphatic amine	Short pot life; room-temperature curing possible; LTS
"Sonite" No. 41	Aromatic amine	Long pot life; low-viscosity liquid; cures at 212°F; postcure at 300°F for optimum properties; HTS
Wyandotte Chemicals Corp.		
Monolene	Monopropylene oxide adduct of ethylenediamine	Short pot life; low-viscosity liquid; room-temperature curing; lighter colored products; LTS
(Note: Addition of Quadrol, the tetrapropylene oxide adduct of ethylenediamine, increases pot life and reduces exotherm when used in conjunction with Monolene.)		

[1] LTS = low-temperature service (up to 200°F.); HTS = high-temperature service (above 200°F.).
[2] "Non-toxic" materials actually may be "practically non-toxic" or "slightly toxic."

other industrial applications where damaging corrosive atmospheres may exist.

Adhesives

Epoxy-base adhesives have found extensive usage in joining a wide variety of materials to one another, particularly where high strength and ease of application are desired. Curing can be effected with the application of just sufficient pressure to insure positioning of the adherend faying surfaces. Excellent gap-filling characteristics often are an attractive feature.

A large number of commercial products are available for low-temperature service (up to 200°F.). Some of these can be cured at room temperature, though for maximum strength a heat cure generally is desirable. Two-part systems require mixing just prior to use and have a limited working life. Several one-part systems now are available which require no mixing, have an extended storage life, but require curing at elevated temperatures.

Formulations are available suitable for structural service at temperatures up to 500-600°F. (e.g., epoxy-phenolic adhesive tapes). Adhesives for service at elevated temperatures (above 200°F.) require curing at temperatures above 300°F.

Major applications of epoxy-base adhesives are in the bonding of metals and reinforced plastics; wood, most rubbers, ceramics, and many thermoplastics also are bonded. Notable exceptions are silicone rubber, fluorinated polymers (e.g., Teflon and Kel-F), polyethylene, and some vinyls. Chemical treatment of Teflon can result in fair bonds.

Because volatile by-products are not given off during cure, large areas can be joined with minimum precautions. Sandwich constructions, made by joining honeycomb and other core materials to various types of facings (or skins), such as metals, plastics, and glass plate, are finding increased usage in load-carrying structures (especially aircraft and missiles), thermal insulation (especially for refrigeration), and

decorative applications (e.g., office partitions, table tops, and skylights).

Resistance to various chemicals and weathering permits the use of epoxy-base adhesives wherever corrosion-resistant joints are necessary.

The inherent brittleness and the concomitant poor peel resistance of epoxy-base adhesives frequently are minimized by employing adhesive primers with excellent "peel strength." More flexible adhesive formulations are available (containing suitable flexibilizers), but at a sacrifice in strength at elevated temperatures and in resistance to creep.

Laminates

Reinforced plastic laminates are fabricated using epoxy resins with various types of reinforcements, e.g., glass fabrics, mats, and rovings, asbestos felts, paper, cotton, nylon, Dacron, and other fabrics, and metal foils. Compared with other resins, laminates from epoxy resins provide the optimum mechanical-strength properties, including wet strength retention, as well as excellent electrical properties for service at temperatures up to about 300°F.

Vacuum-bag molding, contact molding (especially with tacky, liquid resins i.e., by wet lay-up), and matched-die molding are the most common fabrication techniques. Pressure-bag molding is employed less frequently.

Curing agents used with liquid epoxy laminating resins include diethylenetriamine (for rapid cures at room temperature, by wet lay-up); diethylaminopropylamine (for curing at moderate temperatures, by wet lay-up); and aromatic amines, especially meta-phenylenediamine and mixtures (these require curing at elevated temperatures and then postcuring for optimum properties, by wet or dry lay-up).

Dicyaniamide is frequently used as a curing agent with the solid resins. Reinforcements are impregnated with solutions prepared by dissolving the ground resin-curative mixture in volatile solvents (e.g., ketones and water), and then drying. Such systems are nontacky and have a long storage life; however, they require dry lay-up techniques and curing at elevated temperatures (above 300°F.) under moderate pressures (25 to 200 p.s.i.).

Epoxy-phenolic blends provide improved heat resistance. Blends with furan resins result in reduced material costs and possible improvements in mechanical properties. Epoxy-Thiokol polysulfide blends and epoxy-polyamide copolymers provide greater toughness and impact resistance.

Epoxy laminates are ideal for structural and electrical applications. Radomes, electrical terminal boards, printed electronic circuits, aircraft skins, facings for honeycomb sandwich structures, ducting, pipes, tanks, and pressure vessels are typical. Patching of automobile fenders represents a potential market.

The filament-winding process, employing continuous glass roving and epoxy resin, provides an ideal means for fabricating spherical and other intricate shapes. When suitable liner materials are included, such structures are suitable for containing gases and liquids at pressures of several thousand pounds per square inch.

Excellent thermal insulating characteristics have resulted in numerous rocket and missile applications.

Shatter-resistant characteristics, coupled with high strength-to-weight ratios, have led to their use in many pressure vessels, primarily for military applications.

Castings

A wide selection of modifiers and curing agents can be employed with liquid epoxy resins to produce castings for numerous applications. In addition to the tooling field, epoxy casting resins are widely used in the electrical and electronics industries. Delicate electronic components, such as miniaturized tubes, capacitors and resistors, connectors, rectifiers, transformers, and motor stators, frequently must be protected against humidity, heat, weathering, chemicals, vibration, and other adverse service conditions. The low shrinkage (less than 2%) of epoxy casting resins, in addition to excellent electrical, chemical, and mechanical properties, has resulted in their widespread use for these purposes. Formulations generally are required to be fluid and to cure at low to moderate temperatures with a low exothermic heat rise. Fillers, which increase viscosity, help to minimize exotherms by dissipating the heat developed during cure; also, they reduce shrinkage.

The excellent wetting characteristics of epoxy resins can provide excellent impregnation not only of electrical components but also of structures such as porous castings (for sealing purposes).

In order to reduce viscosity, diluents (e.g., allyl glycidyl ether and phenyl glycidyl ether) frequently are added. Ten parts of diluent added to 100 parts by weight of resin will reduce the resin viscosity to a considerable degree without seriously impairing strength properties.

Tooling

Plastic tools and dies are being fabricated from epoxy resins for use in the automotive, aircraft, and other industries. Applications include metal-forming tools for stretching, drawing, etc., assembly and machining fixtures, locating fixtures, foundry patterns, vacuum forming dies, and numerous others. Even precision tools such as Keller models, checking fixtures, drilling fixtures, and matched dies can be made, taking advantage of the low shrinkage of epoxy resins especially when filled with inert materials, to obtain dimensional reproducibility.

Fabrication techniques consist primarily of laminating and casting. Laminates are used for thin tools and when maximum mechanical strength is required. For tools over 1 in. in thickness, casting is more suitable and considerably cheaper.

Foams

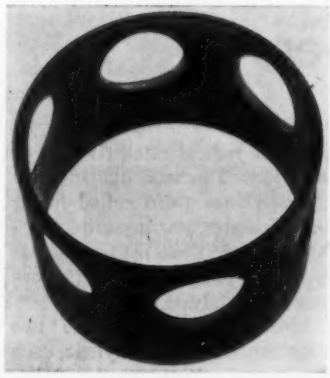
Epoxy resins can be converted into foamed or expanded plastics which are suitable for many applications, e.g., encapsulation of electronic components, thermal insulation, and as core materials in sandwich-type structures.

Two-component liquid systems are available which have relatively short working lives. Heat is essential to induce foaming, and

may be supplied externally or result from the exothermic heat of the curing reaction. When potting delicate components, or if a very uniform cell structure is desired, high exotherms must be avoided. Additional heat curing generally is recommended after the foaming operation. An excellent foamed cell structure has been reported for an epoxy-polyamide system, which can be prepared with external heating, using dimethyldinitrosoterephthalamide as the blowing agent.

Single-component epoxy foaming resins, in powder form, have extended storage lives.

In both types, a chemical blowing agent must be included in the formulation, as well as the curative. The blowing agent is responsible for liberation of the gas which produces the expansion of the epoxy resin. Wetting agents also are frequently included. When necessary, a volatile liquid may be added in order to absorb some of the exothermic heat.



Molding compounds

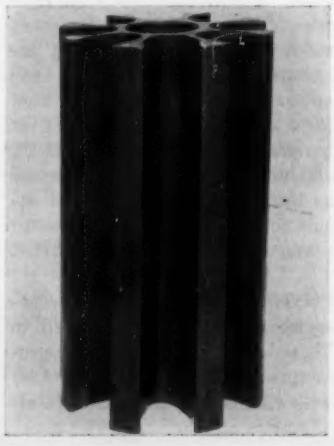
Materials are being developed, based on epoxy resins, which are expected to provide dimensionally reproducible parts fabricated by compression and transfer as well as plunger molding. Several molding materials now are commercially available. Powders or viscous pastes (premixes) may be employed. Inert filler materials are essential components. Molding materials require molding cycles of only 1 to 10 min. at temperatures of 250 to 350° F. and pressures of a few up to several thousand pounds per square inch.

Excellent adhesion (to inserts), chemical resistance, and mechanical strength, versatility in formulating, and low mold shrinkage are desirable attributes. Release from mold or cavity surfaces can be troublesome, and requires precautions with respect to mold design and the use of release agents. Fire- and heat-resistant characteristics can be introduced by proper selection of curatives.

Miscellaneous uses

Low-molecular-weight epoxy resins are used as *stabilizers* for chlorinated vinyl polymers, notably polyvinyl chloride, polyvinylidine chloride, and copolymers, due to their ability to act as acid (HCl) acceptors.

Modified epoxy resin formulation used for glass-reinforced nozzle adapter for rocket motor withstands high temperatures



Polymeric-type epoxy *plasticizers* for vinyls are available, some of which also serve as heat and light stabilizers. For low-temperature flexibility, a monomeric epoxidized ester is available; it shows promise in plastisol formulations. Such materials permit the processing of vinyls at higher temperatures.

Epoxy-base *putty* and *solder* compounds (in paste or stick form) are finding many industrial uses. These are highly filled (e.g., with aluminum dust or iron powder) epoxy resins, which are spread over the area to be covered, and cured in place. Finishing operations such as drilling, filing, and sanding are readily performed. Typical applications include the repairing of metal and plastic tooling and dies, and automobile body and fender repairs.

Investigations are being conducted on the possible uses of epoxy resins in combatting *dental* problems, especially tooth repairs. Good adhesion to enamel and dentin are attractive advantages.

Cements and *mortars* based on epoxy resins are used in joining brick or tile in floors and tanks, where their chemical resistance offsets high material costs.

Low shrinkage of epoxy resin permits close dimensional reproducibility in precision casting of tool

Ethylene Polymers

Polyethylene is the second largest and the fastest growing of all plastics materials. By the end of 1955, the rate of consumption of conventional polyethylene approached 400 million lb. and in 1957 it is nearing 700 million lb. If the newer high-density polyethylenes reach expected production, total polyethylene consumption in the United States may reach 1 billion lb. by 1960.

Basically, polyethylene is synthesized by the polymerization of ethylene at elevated temperatures and pressures in the presence of suitable catalysts. Conventional low-density polyethylene (also known as branched polyethylene, high-pressure polyethylene, etc.) requires very high synthesis pressures (15,000 to 30,000 p.s.i.) and uses free radical catalysts such as peroxides. The stiff high-density polyethylenes (also called linear polyethylenes, low-pressure polyethylene, etc.) are made at lower synthesis pressures, using coordination catalysts.

Although these are the two main classes of polyethylene, each constitutes a large family of different resins.

Fundamentally, a polyethylene molecule is made up of a long chain of carbon atoms, each with two hydrogen atoms attached. The molecule usually contains between 800 and 100,000 carbon atoms.

During the synthesis process, the active end of a growing molecule sometimes dislodges a hydrogen atom from the middle of another molecule, producing an active site which results in the growth of a long-chain branch at that point. As might be expected, a polyethylene containing a sizable proportion of such branched molecules exhibits different flow properties in the molten state than one without long-chain branching.

A second type of reaction which may occur during the synthesis process results in the formation of many short branches (2 to 4 carbon atoms in length) at irregular intervals along the main chain and the longer branches. These short branches are responsible for the great differences in solid state properties which exist between the branched and linear types of polyethylene.

Crystallization

One of the properties of the type of hydrocarbon chain found in polyethylene is a tendency to crystallize. Crystallization is said to have occurred when a number of chains, lying in approximately parallel alignment, assume a more compact configuration, producing a small crystal or "crystallite." A single hydrocarbon chain or long branch may pass through

This article is based on information supplied by the following companies: E. I. du Pont de Nemours & Co., Inc.; Bakelite Co.; Spencer Chemical Co.; Hercules Powder Co.; Phillips Chemical Co.; and Eastman Chemical Products. Recent Developments and References were prepared by the editors.

RECENT DEVELOPMENTS

Lead-filled polyethylene (*Leadolene,* Telectro Industries Corp.), for use in radioactive shielding applications, produces a homogeneous casting that is smooth-surfaced, resistant to oxidation, and recastable without loss of material. The composition is 95% lead and 5% polyethylene, but this can be varied to meet specific requirements. The lead content shields against beta and gamma rays, the hydrogen (supplied by the polyethylene) against neutrons.

A fungicide-treated industrial paper material (*X-Crepe N,* Cincinnati Industries, Inc.) uses polyethylene as a moisture-vapor barrier. The material is a cross-creped heavy-duty paper with all-directional stretch. Polyethylene is laminated between two plies of the paper which is then coated on one side with polyethylene. Fungicide is applied to the paper side or exterior of the case liner. It is recommended for case liners and other industrial uses wherever a strong, clothlike, stretchable, baceteriostatic, polyethylene-coated material is required.

An irradiated extrusion grade polyethylene compound (*E-234,* General Electric Co.) is being evaluated for use in wire coating and insulating. The compound can be extruded directly onto wire as easily as conventional polyethylene. Also in the development stage are a semiconducting irradiated polyethylene tape for power cables, a new grade of tape to withstand physical stress at temperatures higher than 350° C., and heat-shrinkable tubing for use as lead insulation, as ground insulation on small component parts, and as a corrosion barrier.

Polyethylene plumbing accessories are now being offered in high-density material by a manufacturer (American Vulcathene) who claims that his series (*Universal*) of wastes and traps made of this material have high chemical resistance and are capable of handling boiling water continuously.

A synthetic mineral wax (*FT-300,* Dura Commodities Corp.), produced by the synthesis of carbon monoxide and hydrogen, can be blended with high-pressure polyethylene to increase its rigidity. These mineral waxes have approximately the same melting point as high-pressure polyethylene and have a high softening point. They are said to be superior to paraffin wax, petroleum wax, or other mineral waxes for maintaining heat resistance of the polyethylene.

Addition of a hard hydrocarbon wax (*Paraflint,* distributed by Moore & Munger) to polyethylene is said to result in a molding compound with a higher melt index than the polyethylene alone and also to improve the feel, gloss,

several crystallites, with disordered or "amorphous" portions between. The presence of short chains, however, restricts the formation of crystallites.

The amorphous and crystalline forms differ in several properties, of which two may be cited by way of illustration. Compared with the amorphous material, the crystalline material is harder and stiffer (because the closely parallel chains are bound together) and it is denser. The higher density in the crystallites is due to the "close-packing" of the resin chains in the crystalline lattice. X-ray measurements indicate a density of 1.00 for the crystallites. The density of the amorphous regions are not known with certainty since various types of measurements lead to figures ranging from 0.76 to 0.85.

In any resin, therefore, the relative percentages of crystalline and amorphous materials will determine the density of the whole resin. A completely (100%) crystalline resin would have a density of 1.00 and a wholly amorphous resin would have a density in the vicinity of 0.80. Between these extremes, density and percent crystallinity vary.

Since many of the properties of polyethylene, therefore, depend on the density or crystalline content of the resin, nomenclature used in this article will be based on *density*—low-density for the conventional polyethylenes and high-density for the newer polyethylenes. The intermediate-density materials will also be discussed.

Melt index

The amount and types of branching, as well as the average molecular size, affect the flow properties of the molten polyethylene in a complicated manner. To simplify this complex problem, it is convenient to determine the fluidity of the melt under a set of rigidly specified conditions. The number of grams of molten polymer which will flow through a standard orifice at a standard temperature and pressure in a given time is called the *melt index* of the polymer. Thus, the higher the melt index, the more fluid is the melt. This test provides a rough measure of the behavior to be expected from the resin under actual fabrication conditions, as well as its performance in certain use-tests which depend on molecular weight.

Molecular weight

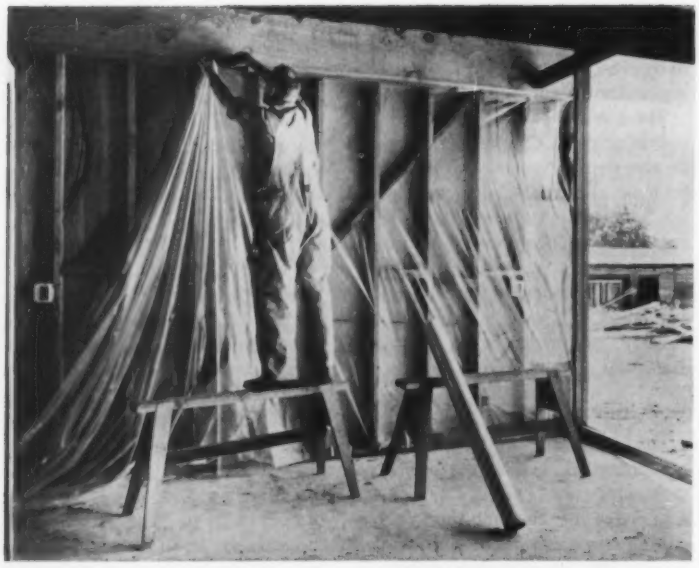
Unfortunately, it is sometimes observed that melt index is not a true indication of the ease of flow during processing. This fact stems from the non-Newtonian nature of molten polyethylene. In a Newtonian fluid, the amount of flow is always directly proportional to the stress applied. In other words, the viscosity is the same whether the stress is little or great. In the case of polyethylene, on the other hand, the greater the applied stress, the lower the viscosity becomes. The amount of departure from Newtonian behavior is greatly affected, in polyethylene, by the breadth of the *molecular weight distribution*. If two polyethylenes of the same melt index

---

and stiffness of the finished product. This wax, which has a low viscosity and crystalline structure, melts at 215°F. It can be blended with both the high- and low-pressure-processed polyethylenes and is said not to impair impact and tensile qualities.

Low-pressure polyethylene extruded sheet (Campco Div., Chicago Molded Products) can be readily vacuum formed. It is available in both Ziegler and Phillips types. Specific gravity is 0.945 for Ziegler and 0.96 for Phillips, and heat distortion points at 66 p.s.i are, respectively, 140 and 168° F.

Polyethylene film (*Visqueen*, Visking Corp.) has been found by a Philadelphia construction firm (Robert E. Lamb & Sons) to be useful in separating freshly-poured concrete panels used for walls in tilt-up slab construction methods. The film may be used more than once and may later be used over again for various other types of applications at the construction site.



Vacuum pouches made from a specially-treated polyethylene film (Cryovac Co., Div. of W. R. Grace & Co.) have extremely high resistance to the transfer of gas, air, and moisture. The bags are intended for packaging sliced food products sold in consumer-sized units.

A new ink system (*RP series*, Claremont Pigment Dispersion Corp.) for gravure printing on treated polyethylene offers all the performance properties of conventional gravure inks. Available in a full color range, including metallics, these storage stable, concentrated inks provide the printer with the flexibility necessary to adjust inks for printing with engravings of any depth and pattern.

A line of polyethylene toys (Payton Products, Inc.) is treated with a bacteriostatic compound (*Corobex*, Bex Industries, Inc.) used to make molded plastics, textiles, and other products germproof, self-deodorizing, mold-static, and fungus-static.

Color dispersions for injection molding (*Formacolor LP*, Westchester Plastics, Inc.) and extrusion (*Unicolor LP*) of linear polyethylene are mixed in a linear polyethylene base to form masterbatches which can then be extended by the molder or by the extruder.

A new type of plastic pipe (*Klearcor*, Western Plastics Corp.) is composed of a core of unpigmented polyethylene covered by an outer sheath with high carbon-black pigment concentration. The outer sheath which serves as an added safety factor and as an ultra-violet shield is guaranteed by the manufacturer not to separate from the clear core.

Promising market for polyethylene film is as an easily-installed moisture vapor barrier material in side walls of homes and buildings. (Photo, Visking)

have different molecular weight distributions, the resin of narrower distribution will have the greater apparent viscosity at stresses above that applied in the melt index test. Conversely, the resin of broader distribution of molecular weights will have the higher apparent viscosity at very low shear stresses.

Selecting the polyethylene

Barring additives or contamination, any polyethylene can be defined by the values of these three parameters: density, melt index, or molecular weight. The effects of the three parameters, taken separately, are as follows:

1) *Density:* As the density increases: a) stiffness increases; b) yield strength increases; c) Graves tear strength increases; d) Elmendorf tear strength decreases; e) resistance to creep increases; f) Vicat softening temperature increases; g) impermeability to liquids and gases increases; h) brittleness temperature decreases; i) film brittleness increases; and j) flex life decreases.

Density has no effect on the properties of the molten polymer, since crystallites do not exist in the melt.

2) *Melt index:* As the melt index is increased: a) melt fluidity increases (viscosity decreases); b) melt "drawability" increases; c) film coefficient of friction increases; d) tensile strength decreases; e) Elmendorf tear strength decreases; f) resistance to environmental stress cracking decreases; g) low-temperature toughness decreases; and h) Vicat softening temperature decreases.

3) *Molecular weight distribution:* A decrease in the breadth of the molecular weight distribution has these effects: a) tensile strength increases; b) film brittleness decreases; c) low-temperature toughness increases; d) Vicat softening temperature increases; e) resistance to environmental stress cracking increases; and f) ease of processing at high shear stresses decreases.

It is evident from the foregoing that once a prospective fabricator or user of polyethylene decides on the properties which are most important to him, he can select the best resin for his purpose by the proper choice of density, melt index, and molecular weight distribution.

LOW-DENSITY POLYETHYLENE

Ethylene was first polymerized by Fawcett and Gilson in the late 1930's. They discovered that, when ethylene was subjected to pressures of the order of 1000 to 2000 atmospheres and temperatures in excess of 100° C., in the presence of oxygen or peroxide catalysts, a solid polymer was formed. Most of the low-density polyethylene manufactured today is made by this basic process.

Chemical structure

The properties of polyethylene resin depend on the chemical structure of the polymer molecules. The simplest structure which can be drawn for the polyethylene molecule is:

$CH_3- - -CH_2CH_2CH_2CH_2- - -CH_3$

Evidence from infra-red spectra and other sources indicates that the chain is not linear and regular as shown but is interrupted by various irregularities. Small amounts of unsaturation are present, but the main type of irregularity is branching. According to recent evidence, these branches are probably four carbons long in resins made by the high-pressure process.

To appreciate the effect of branching, first consider straight chains without branching. Without branches to protrude and interfere, the chains have a good chance of lining up parallel with other chains. The result of the tendency to parallelization is a structure in which any one chain is somewhat curled, but all along the length it is parallel with other chains and close to them. When the possibility of parallel alignment of simple molecules of the polyethylene type exists, it is usually found that crystallization or freezing take place. In the crystal, the spatial arrangement of the molecules is in a definite geometric configuration.

INTERMEDIATE-DENSITY POLYETHYLENE

In the past year, commercial quantities of a new type of intermediate-density polyethylene have become available. These intermediate-density resins have properties that fall in-between the high-density and low-density types, although they are made by a modification of the high-pressure process used for making the low-density polyethylene.

The unique performance of this

intermediate range stems from the fact that, while the physical properties of polyethylene vary with the density, the relationship is not a straight-line function in most cases. It just happens that the density property lines fall in such a way that in many important properties the greater part of the improvement possible by increasing density, has already been obtained in this range. One of the limitations to the use of the low-density polyethylene, for example, is its permeability to many liquids and gases. This permeability is greatly decreased by an increase of density, and about 80% of the improvement possible has already been obtained in the intermediate range. Heat resistance is in the same category. The largest and most significant increase in heat resistance has already been achieved in the intermediate-density range. In addition, some of the properties which are sacrificed because of higher density, e.g., impact strength, fold endurance, etc., reportedly will show less of a loss in the intermediate-density range.

The range on the melt index scale where the transition between waxy and plastic polyethylene appears is strongly influenced by density. In low-density polyethylene a melt index of 50 is still safely on the plastic side, in high-density polyethylene a melt index of 1 is already near the transition range to wax. In the intermediate-density range, the edge of the transition to the waxy state is in the vicinity of melt index 8 or 10 so that materials of good properties can be made up to a melt index of 2 or 3. This will generally permit normal processing.

TABLE I: Comparison of properties of polyethylene in the three density classes.

Property	*Low-density*	*Intermediate-density*	*High-density*
Density	0.91-0.93	0.93-0.94	0.94-0.96
Hardness (Shore D)	40-50	50-63	63-70
Stiffness modulus, p.s.i.	10,000-25,000	25,000-50,000	50,000-140,000
Tensile strength	1500-2000	2000-2800	2800-6400
Elongation, %	200-550	200-500	25-500
Heat resistance, °F.	212	240	250

HIGH-DENSITY POLYETHYLENE

Polyethylene having a higher density, and significantly different properties from the familiar material, is produced by a much different process than the previously-discussed types. In this process ethylene is dissolved in a solvent at moderate pressures, usually 500 to 1000 p.s.i., and the solution is placed in contact with one of a number of widely differing catalysts which are insoluble in the solvent. Active centers on the surface of the catalyst polymerize the ethylene by means of a co-ordinating or directing mechanism which, in most cases, results in a "straight chain," or substantially unbranched polyethylene molecule.

The absence of branches permits the molecules to pack together more closely and results in a denser material.

In all polyethylenes there is some tendency for the molecules to conform to each other to form crystallites. The unbranched material is able to do this more completely. The term "straight chain" is often misleading since the configuration of the molecule is actually coiled. When these coils crystallize they form an interlocked spiral crystallite. A number of these crystallites grow out from a center into a structure called a spherulite. The general picture is not unlike a mass of well-entangled fine springs.

In the low-density polyethylene, crystallite and spherulite are embedded in a considerable amount of amorphous material which is responsible for the flexibility, and also for the permeability. This amorphous material also adds to shock resistance by distributing stresses. In the high-density material little of such yielding material remains. This makes the size of the spherulites extremely critical. Slow cooling of the melt, or any considerable length of service at elevated temperature results in growth of the spherulite to a size at which stress concentrations appear. When this happens the material becomes extremely brittle.

The high-density materials are therefore stronger, stiffer, less ductile, more heat resistant, and less permeable. See Table I, above, for comparison of properties.

The main difference between these and the intermediate-density resins is that the density change has gone so far that the material is hardly recognizable as polyethylene and should not be considered merely as another or an improved polyethylene. It is in many ways an entirely new type of material.

APPLICATIONS

All the polyethylenes—low-density, intermediate-density, and high-density—can be molded or extruded into a wide variety of useful products. Some of the more outstanding market areas for the various polyethylenes are discussed below.

Injection molding

Polyethylene has grown rapidly in the molding field because of its "nonbreakability," flexibility, ease of processing and col-

Typical of the king-size pieces being molded of polyethylene is a 10-gal. colorful garbage can. (Photo, Eastman Chemical)

oring, chemical resistance, and low cost. The molding industries account for about 17% of the polyethylene produced.

For injection molding, polyethylene in pellet form is available with melt indices ranging from 1.5 to 20. Molders may choose a type that best suits their requirements for molding performance and physical properties. The high melt index types permit molding of large objects such as wastebaskets and garbage cans and also offer the additional advantages of superior gloss. Lower melt index types find use in applications requiring greater rigidity, strength, and resistance to environmental cracking.

About half of the low-density material goes into such housewares as bowls, buckets, wastebaskets, garbage cans, containers, etc. Other large outlets for molded low-density polyethylene are closures for squeeze tubes, spouts for detergent cans, and shoe parts.

A large proportion of high-density polyethylene will undoubtedly also find a place in the field of molded objects. Because equal stiffness can be obtained with thinner cross-sections, it will be more economical in many molded items than low-density material. Its high heat resistance will also open up large fields now denied to the lower-softening-point materials.

Intermediate-density materials which fall in the range between these two should also find new uses. They have improved stiffness and gloss, without much sacrifice of flow properties, coupled with improved heat resistance.

Film and sheeting

To date, film has consumed more polyethylene than any other fabricated form. Since 1953, more than a third of all polyethylene used in the U. S. has been converted to film. Over 80% of the film produced now goes into the packaging of foods, textiles, toys, hardware, machinery, and chemicals. Although the importance of polyethylene film in the packaging industry will undoubtedly continue to increase, some non-packaging applications are expected to grow even more rapidly in the near future. Agricultural and construction uses, in particular, are just gaining momentum and can be expected to expand tremendously. Polyethylene film provides the means for revolutionary new techniques of agriculture, leading to increased yields with reduced labor. In the construction industries, it is finding ready acceptance as a water-vapor barrier, and as a means of temporary protection of materials from the weather.

Polyethylene film is produced mainly by extrusion, either from a flat die with water quenching or by the blown-tubing method. Some film is produced by calendering but the difficulties of this process have greatly limited its commercial development. Some of the new films provide exceptional clarity combined with improved slipping and blocking characteristics. When special properties are required, the user may select one of the blends of polyethylene with rubber or other materials. Film made from high-density polyethylene displays excellent slip properties, and is completely nonblocking. The flat die and water tank process produces high-density film having excellent transparency and surface quality. "Blown" film may be somewhat less transparent than low-density film. In both cases, the higher stiffness modulus is quite apparent, and this may be desirable for pushing film through automatic packaging machinery.

The technique for sheet extrusion is almost identical to that used for impact-type styrene sheet. Outstanding surface quality can be achieved with a flat die and a three-high roll stack take-off. For example, a combination of 390° F. stock and 220° F. roll temperatures has produced a high-gloss surface which was not lost during subsequent forming operations. Furthermore, sheeting that will not deform when reheated can be produced by avoiding "draw-down," i.e., sheet thickness is as great as, or greater than, the die opening.

The large-scale use of heavy sheeting, however, has been retarded by the lack of well-developed fabrication techniques. As the necessary techniques are worked out, and sheeting with the required properties becomes available, a great increase in the production of polyethylene objects by the thermoforming of heavy sheet will occur. At least initially, the bulk of this effort will probably be in the packaging field. Later, many items now produced by the more expensive injection molding process will undoubtedly be thermoformed. High-density polyethylene is a particularly attractive material for this process because of its greater stiffness, and techniques are already being developed for forming it.

Barrel-like 13-gal. polyethylene drum is light in weight, unbreakable, and corrosion-resistant. (Photo, Plax Corp.)

Electrical insulation

High electrical resistivity and good dielectric characteristics, particularly at high frequencies, have made polyethylene an important material in electrical insulation. About 15% of the polyethylene now produced is used for electrical insulation or jacketing. During World War II, nearly all the available polyethylene was used for insulation in communication service, particularly high-frequency applications. Polyethylene is used as an outer jacket on power cables, telephone lines, television lead-in wire, and appliance wire where it serves as both insulation and as a protective barrier against moisture, weathering, and abrasion. Some

of the higher melt index types are also used, usually compounded with polyisobutylene or synthetic rubber to improve their environmental crack resistance. However, improved crack resistance is usually obtained by the use of low melt index grades of resin. High-density polyethylenes are run in the cross-head extruders normally used for wire coating, and make possible the production of wire having greatly increased resistance to heat and abrasion. Its greater strength and resistance to damage during manufacturing operations will permit the use of thinner insulations. Low-density polyethylene may be largely replaced in this field.

Irradiated polyethylene tape is wrapped around cable containing telephone wires. The tape is made highly resistant to heat and environmental stress-cracking by bombarding conventional polyethylene film tape with high-velocity electrons. (Photo, General Electric Co.)

Pipe

Polyethylene pipe is finding steadily increasing acceptance for farm, mine, and home uses, primarily in the transportation of cold water. It is available in sizes ranging from ½ to 6 in. in diameter. Its principal advantage over other plastic and metal pipes is its flexibility, which allows lengths up to 1500 ft. to be coiled for shipment. This results in great ease of installation. Other advantages are its immunity to rupture through freezing, and complete resistance to corrosion. Polyethylene pipe is colored black (with 2 to 3% of finely divided carbon black) for protection against ultra-violet light. At present, pipe accounts for about 13% of the polyethylene produced in the U. S., and this proportion will probably not change greatly in the next few years.

The position of high-density polyethylene in the pipe field has not yet been established, but it is not expected to compete seriously with the more flexible materials in their present uses. One of the desirable features of low-density polyethylene pipe is its flexibility, which permits marketing in easily-handled coils, whereas the higher stiffness modulus of the high-density type will necessitate shipment in straight lengths, with the accompanying need for joints. In many installations, however, the increased heat resistance of the high-density pipe will be of greater importance than the reduced flexibility. Long-time burst strength of high-density pipe is only marginally better than low-density pipe. Joining the semi-rigid, high-density pipe with standard threaded joints has been found to be fully practicable, and short-term bursting tests have shown that properly assembled threaded joints are not points of weakness. For the production of pipe, the extended mandrel technique has been found to be the most dependable and trouble-free.

Coatings

Of the various methods of coating other materials with polyethylene, only extrusion-coating is of commercial importance at present. In this process, a very thin film of polyethylene is extruded directly onto a moving web of paper, aluminum foil, or other sheet material. About 7% of the polyethylene consumed in the U. S. goes into extrusion-coating applications. The great bulk of this is extruded onto paper for multiwall bags, wrapping and lining papers, and pouch bags. Coated aluminum foil is heat-sealable, and provides a package which is absolutely waterproof. Cellophane and polyester film coated with polyethylene are finding increasing acceptance for packaging applications requiring greater strength, impermeability, or heat resistance than would be provided by polyethylene alone. Fabrics have been extrusion-coated with polyethylene to render them waterproof, or better able to retain finely powdered materials. Nonwoven mats of cellulose fibers are coated to produce disposable baby diapers and hospital sheets. A probable large future application is the coating of board stock for milk cartons and other liquid containers.

To all these combinations, low-density polyethylene contributes wear resistance, heat-sealability, form retention, and moisture resistance. The lower permeability of high-density polyethylene may lead to its use in extrusion-coating, although modified coating methods will be required.

Metal surfaces can be coated with a heavy layer of polyethylene by flame spraying. In this process, a stream of finely powdered polyethylene suspended in an inert gas is introduced through the nozzle of a torch resembling a gas welding torch. The metal surface is first preheated by the

flame, and the molten particles stick to it and fuse together to form a continuous coating. A fluidized-bed technique is used to coat small irregularly-shaped metal objects. The object to be coated is first heated, and then suspended in a "boiling" bed of finely divided polyethylene. The heat of the object melts the particles on contact, resulting in a uniform coating of controllable thickness.

Bottles and tubes

Polyethylene can be blow molded into bottles and collapsible tubes for cosmetics, drugs, foodstuffs, and chemicals, and has had particular success in baby bottles. In this field, polyethylene has gained great popularity because of low cost, resistance to breakage and corrosion, "squeeze" flexibility, and sales appeal. In the blow molding process, an extruded tube is formed to shape in a mold by air pressure. Large carboys and drums can be made by welding or blow molding.

Special polyethylenes have been developed to meet the particular flow requirements of various custom processes. In some packaging applications, the use of polyethylene alone has been restricted by the diffusion of essential oils and other volatile substances through the wall of the container. However, this limitation has been reduced by the use of lining compounds.

High-density polyethylene can be processed in conventional equipment in accordance with the usual procedures for making bottles of low-density polyethylene. For many applications, the increased rigidity and heat resistance will outweigh the reduced flexibility. "Squeeze bottles" can be made by designing plane or slightly curved faces which will display a diaphragm or "oil-can" action. Extruded polyethylene tubing fitted with two metal ends also shows possibilities. The lower permeability of the high-density bottles should permit a greatly broadened use of plastic bottles and containers in the packaging of cosmetics, pharmaceuticals, and miscellaneous chemicals.

Work is also being done with linings for polyethylene bottles that will decrease permeability.

Clothes sprinkler is molded of polyethylene to take advantage of the material's resiliency and eye appeal. (Photo, Bakelite)

Filaments

This market is relatively small in low-density polyethylene, and complete displacement can be expected, together with rapid growth in total input. Filaments produced from high-density polymers can be oriented by stretching 800 to 1000% and have shown tensile strengths comparable to the best synthetic fibers, with excellent abrasion resistance. The combination of low cost, high-tensile, good chemical inertness, and good heat resistance should be of real value in cordage, fish nets, filter cloths, upholstery, and the like.

Since the high-density polymers are still simply polyethylenes, they require the usual protection from the degrading effects of oxidation and sunlight. Commercial anti-oxidants have proved effective. Carbon black is still the best light absorber for wire, pipe, and other items that will be subjected for any length of time to outdoor exposure.

Miscellaneous uses

There are a number of minor applications for polyethylene which, in total, account for an impressive quantity of material. Thick compression molded slabs are used in the shielding of nuclear reactors. Thinner sheets are used in the construction of tanks, tank linings, and many types of chemical process equipment. Small-diameter tubing is used in aerosol dispenser cans, automobile battery separators, industrial instrumentation, and medical applications.

Other uses for polyethylene are potting delicate electrical mechanisms by injection molding and centrifugal casting of large tubes or pipe. Low-molecular-weight polyethylenes are used in emulsions, wax blends, and in rubber processing.

Fluoroethylene Polymers

Polytetrafluoroethylene

BY E. D. CHAMPNEY, JR.*

Polytetrafluoroethylene resins are high polymers of tetrafluoroethylene created by polymerization under carefully controlled conditions. As a consequence of having a molecular structure consisting of carbon and fluorine atoms, they possess a unique combination of outstanding chemical and physical properties. This is a result of the true fluorocarbon system where the primary bonds in the polymer chain are very strong, the secondary valence forces between adjacent chains are weak, and the symmetrical arrangement of fluorine atoms forms an impenetrable sheath protecting the carbon chain.

Tetrafluoroethylene resins are produced as granular powders for compression molding, as special powders normally used with an extrusion aid to produce extruded articles such as insulated wire, and as aqueous dispersions for coating metals and fabrics.

Properties

In addition to their exceptional heat and chemical resistance, polytetrafluoroethylene articles have many other useful properties. Their low dissipation factor and low dielectric constant make them useful in the electrical industry. These properties are only slightly altered at elevated temperatures.

Another unusual property of polytetrafluoroethylene is the material's exceedingly low coefficient of friction—lower than that for any other solid—which makes it useful as a bearing material. The static coefficient is equal to the dynamic value; thus, polytetrafluoroethylene resin does exhibit a slip-stick type of motion.

The impact strength of the material is extremely high but many of the other mechanical strength properties, while adequate for many uses, are not exceptional. Even though many plastics exhibit better properties at room temperature, there are no organic plastics that retain useful mechanical properties over as wide a temperature range. For example, after 1 mo. at 480° F., bars molded of polytetrafluoroethylene showed only a 1% loss in tensile strength.

The value of polytetrafluoroethylene for certain applications can be considerably enhanced by the use of additives. This improves certain mechanical properties and also permits various types of compositions to be tailored to a wide variety of chemical, mechanical, and electrical applications. As an example, resistance to wear by rotating shafts can be increased as much as 500 times through the use of additives. The modified compositions retain most of the outstanding properties of uncompounded polytetrafluoroethylene. Also, elongation and impact strength are lowered, but in most instances these changes do not impair the usefulness of the articles.

Some of the properties of polytetrafluoroethylene, e.g., good thermal and chemical resistance, nonadhesiveness, low dissipation factor, and low dielectric constant

*Product Specialist, E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington 98, Del.

Recent Developments and References were prepared by the editors.

RECENT DEVELOPMENTS

A perfluorocarbon resin (*100-X*, Du Pont) approaches the unique heat and chemical resistance of conventional polytetrafluoroethylene (*Teflon*) but can be extruded in conventional equipment because of its low melt viscosity. The resin has been extruded into film on conventional equipment. It may even be injection molded.

Cementable Teflon tapes, in fibrous glass cloth-reinforced form as well as unsupported, are available (Continental-Diamond Fibre Corp.) in widths from ¼ to 12 in. and in thicknesses from 0.002 to 0.060 inch. Either one or both surfaces is made cementable by treatment with a sodium-ammonia mixture. The material is suggested for use in low-friction and nonsticking chute and hopper linings, electronic components insulation, etc.

Woven glass fabric (Shamban Engineering Co.) coated with polytetrafluoroethylene (*Teflon*) has very low flow under combined heat and pressure. It remains pliable at temperatures below −100° F. and inert up to 390° F. The material does not crack when creased under moderate pressure. Among its applications are conveyor belts for use in food, candy, and other industries in which sanitation and ease of release are important.

Fluorocarbon plastic can be copper-clad without using a resin adhesive thanks to the development of a special bonding technique (International Resistance Co.). The resulting laminate exhibits very low cold flow, zero water absorption, good machinability, and water-repellency.

Fibrous glass cloth impregnated with polychlorotrifluoroethylene (United States Gasket Co., Div. of The Garlock Packing Co.), for linings and surfaces exposed to extreme corrosive conditions, has high chemical resistance to acids (including nitric and hydrofluoric), alkalies, oxidants, and most solvents. The glass cloth is impregnated through half its thickness, and the glass backing furnishes the bonding surface.

High - density polytetrafluoroethylene extruded shapes can be made faster and in a wider range of dimensions on a newly designed extruder (Tri-Point Mfg. & Developing Co.). The equipment produces extrusions with a minimum of orientation and weak spots.

are relatively insensitive to fabrication techniques, while others such as stiffness, flex life, permeability, and tensile strength, are to a large extent under the control of the fabricator.

Processing methods

Tetrafluoroethylene resins are fabricated by a number of techniques including screw extrusion, ram extrusion, preforming followed by pressure or free sintering, extrusion with an extrusion aid (naphtha), calendering, coating and dip-coating, and impregnation. These techniques, while different, have three basic steps in common; 1) cold-forming; 2) sintering; and 3) cooling.

In spite of the outstanding chemical resistance of polytetrafluoroethylene, it is possible sufficiently to disturb the surfaces by special treatment so that they can be adhered to various substrates using a variety of conventional adhesives.

For applications where continuous resin-to-resin joints are required, as in tank linings for chemical process equipment, sheet stock may be heat-bonded. This technique employs a simple contact heater at a temperature of about 710° F. with the aid of a flux and a contact pressure of about 35 p.s.i.

Polytetrafluoroethylene is extremely stable at high temperatures.

Polychlorotrifluoroethylene

BY J. A. JUPA*

The polymer molecule of trifluorochlorethylene consists of a carbon skeleton and two halogens —fluorine and chlorine—present in a mole ratio of 3:1. The chlorine atom contributes to the transparency, moldability, and rigidity characteristics of the plastic, while the fluorine atoms are responsible for its chemical inertness, thermal stability, and zero moisture absorption.

The resulting Kel-F[1] thermoplastic materials have a wide range of molecular weights: high-molecular-weight resins, used for molding and dispersions, are in the range of 300,000 and 400,000 units; lower-molecular-weight materials, existing as oils, greases, and waxes, have boiling points from −110° C. to about 230° C. at 1 mm. Hg. The lower-molecular-weight oils and greases are useful as plasticizers, stop-cock greases, damping fluids, etc.

Molding and extrusion materials: These are hard, dense thermoplastic resins with extreme chemical inertness, thermal stability, and high impact, tensile, and compressive strengths. The materials are supplied as high- or low-density molding powders.

The high-density molding powders are essentially ⅛-in. cylindrical pellets which have a compression ratio of 2:1. The low-density molding powders have a compression ratio of roughly 6:1 and are white, free-flowing powders.

Although there is a plasticizer grade and a flexible type for wire coating and thin-wall tubing, the molding and extrusion materials may be classed generally as rigid rather than as elastomeric plastics (Rockwell Hardness R111 to 115).

Plasticized materials are also available. The plasticizer has the same chemical and electrical properties as the high polymer.

The electrical characteristics of these molding and extrusion materials are also outstanding. The polymer does not carbonize when subjected to electrical arcing and withstands greater than 360 sec. when tested according to ASTM D495-42. Volume resistivity is outstanding over a wide temperature range. Its dielectric strength is 520 v./mil.

Dispersions: Dispersions were developed from polychlorotrifluoroethylene polymers to extend the protection of this material to surfaces that do not lend themselves to the use of molded plastic because of size, design, or construction.

These dispersions consist of finely divided particles of the high-molecular-weight plastic suspended in a volatile organic liquid. Upon heat fusion, the dispersions form a tough, permanent protective coating with all the properties of the original plastic. Dispersions can be applied to many metallic, and certain non-metallic surfaces by spray, spread or dip-coating. Primers are available to increase adhesion.

Antistick characteristics are an important advantage of fluorocarbon dispersion coatings. Glues, inks, paints, greases, meats, waxes, candies, rubber, or casting resins will not readily adhere. When used to coat surfaces of processing equipment, clean-out and shut-down time are reduced and schedules speeded up.

Furane Resins

BY JOHN DELMONTE*

Furane fan housings, 48 in. in diameter, remove acids and acid fumes from pickling tanks in plant. These fans have been installed for at least 10 years, show no sign of deterioration resulting from corrosive fumes or from the weather. (Photo, Haveg Corp.)

Recent Development

A furane-modified vinyl adhesive (*Resin* XV, Furane Plastics, Inc.) is used to bond metal name plates to wood, metal, and ceramic surfaces. The one-component, solvent-type adhesive is applied to the reverse side of the name plate and allowed to dry thoroughly. The name plate is momentarily heated to from 250 to 300° F. and pressed against the clean surface.

With the commercial development of the basic chemicals in the late '30's, furane resins began to make their appearance. Since that time they have become well known to the plastics industry, fulfilling special functions as heat- and corrosion-resistant thermosetting plastics. First they were utilized in conjunction with phenol in the manufacture of molding compounds, and then as polymers of furfuryl alcohol in adhesives and adhesive mortars.

Chemistry

The present industrial prominence of furane resins is due to the work of the late Dr. John Trickey and The Quaker Oats Co. in developing efficient methods for the extraction of furfural from pentosan-rich by-products (such as corn cobs, oat hulls, and —more recently—bagasse). Hydrogenation of furfural to furfuryl alcohol made available a compound capable of self-resinification in the presence of acid catalysts. Tetrahydrofurfuryl alcohol, water-white in appearance, has become valuable in the preparation of various esters for polyvinyl resins. Furan, another furane derivative, is most important commercially as the starting chemical used in the synthesis of commercial nylon. Tetrahydrofuran is one of the most active solvents for polyvinyl resins.

* President, Furane Plastics, Inc., 4516 Brazil St., Los Angeles 39, Calif.

Recent Developments and References were prepared by the editors.

Furane cement is used to lay acidproof bricks to form lining for a large concrete tank. (Photo, Haveg Corp.)

Processes

A few of the more important processes using furane derivatives are as follows:

Furfural (also used as a partial replacement for formaldehyde) + phenol = molding compounds; furfuryl alcohol + dimethylolurea = low-shrink wood adhesives; furfuryl alcohol polymers = resin cements for acid bricks; furfuryl alcohol + formaldehyde = coatings and resin cements; furfuraldehyde + ketones = coatings and resin cements.

Outstanding properties

The properties of the furane resin compounds reflect the characteristics of the chemicals with which they have been reacted (i.e., phenol or urea). However, if pure furfuryl alcohol polymers are examined, the following qualities will be found in the resin:

1) Outstanding penetrating and impregnating qualities as a low-molecular-weight resin.

2) As a cured resin: a) excellent resistance to acids, alkalies, and solvents; b) good thermal stability and retention of strength and corrosion resistance at temperatures of 300 to 400° F.

3) Appearance: Dark, black colors characterize the cured polymers of furfuryl alcohol which cross-link rapidly into a tight, brittle structure.

Resins from furfuryl alcohol form liquid partial polymers and infusible and insoluble solids when reacted with heat and catalysts. Applications include:

1) Plaster of paris impregnants.

2) Cementing compounds for acidproof bricks when mixed with fillers.

3) Corrosion-resistant coatings which cure at low or moderate temperature.

Furfural-ketone resins will form soft solids which in turn will readily dissolve in solvents for use as coatings and adhesives. These have been used as modifiers for epoxy resins.

Inorganic Plastics

Recent Development

A completely inorganic material (*Rosite "M"*, Rostone Corp.), which is cold molded at high pressures and subsequently cured in live steam at high pressure, provides marked arc-quenching under the action of an electric arc. The dielectric breakdown of this material is 60-80 v./mil; the flexural strength, 5000 p.s.i.; impact strength, 0.5 ft.-lb./in. (Charpy); heat resistance, 800° F.; and the water absorption of impregnated material is 0.5 to 1.0% after 24-hr. immersion.

GLASS-BONDED MICA AND THE CERAMOPLASTICS

BY J. H. DUBOIS*

One of the original inorganic plastics materials was glass-bonded mica, first produced in the United States in 1923. Glass-bonded mica is prepared by mixing freshly ground natural micas and a low-melting-point electrical grade of glass. This mixture is preheated until the glass becomes soft, then pressed to the desired shape by either of two methods—the compression molding process or the injection molding process.

For fabricating purposes, sheet and rod materials are formulated with a minimum amount of glass and a maximum amount of mica. A different combination is used to get a high plasticity material for molded products. High dielectric constant materials may be achieved by the inclusion of titanium dioxide or other titanates.

Glass-bonded mica molded products may be used at temperatures up to 650° F.; the fabricating material may be used at temperatures up to 700° F.

Included among the various other desirable properties are total arc resistance, radiation endurance, negligible moisture absorption, total dimensional stability, and freedom from distortion under age and thermal cycling. The thermal expansion coefficient matches closely the ferrous insert materials.

In processing these materials, proper proportions of mica and glass are mixed intimately with about 10% of water. The mixture is preformed under pressure of 4000 p.s.i. and dried to remove excess water. Compression molding is accomplished by heating preforms until the glass becomes plastic and then hot-pressing at 500 to 700° F. at approximately 4000 p.s.i. Most sections require careful annealing after molding.

Injection molding of glass-bonded mica is done by first preheating the charge, which is then manually transferred to the injection cylinder and injected into a closed mold maintained at a temperature of approximately 700 to 900° F. and at pressures from 10,000 to 50,000 p.s.i.

The ceramoplastic materials (Supramica 500, Supramica 555, Supramica 560)[1] are relatively new products composed of Synthamica, a pure, fluor-phlogopite synthetic mica, bonded with inorganic materials which enable them to be used in the 500° C. range for missile and supersonic aircraft components applications. The ceramoplastic materials also exhibit the moldability, the inclusion of inserts, and the ability to mold intricate detail not found in the true ceramic materials. The ceramoplastic materials have been subjected to a radiation dosage of 3.7×10^{18} gamma photons per sq. cm. and 1.7×10^{17} fast neutrons per sq. cm. with no change in dimensions, Rockwell hardness, and electrical resistance.

Included among the various other desirable properties that are important to the missile programs are a thermal expansion match with steel insert materials, absolute dimensional stability, no measurable moisture absorption, total arc resistance, improved machinability (compared with glass-bonded mica), and excellent electrical properties. The matching thermal expansion coefficient facilitates the inclusion of steel reinforcement for highly stressed sections.

Ion Exchange Resins

BY ROBERT W. PERCIVAL* and ALVIN G. WINGER*

RECENT DEVELOPMENTS

Radioactive contaminants may be removed from water by the addition of commercially available ion exchange resins. The Sanitary Engineering Branch of the Corps of Engineers' Research and Development Laboratories says the treatment makes water suitable in 30 min. for emergency drinking.

A new process for "in-situ" epoxidation with cation exchange resin catalysts makes continuous flow column techniques practical for the first time (Becco Chemical Div., Food Machinery & Chemical Corp.). The process overcomes resin attack, thus substantially extending the working life of the resin as well as retaining its catalytic action.

A new series of ion exchange resins for use in chromatographic analysis (*CG*, Rohm & Haas Co.) is chemically identical to standard and analytical grade (*Amberlite*) exchangers, but the particle size is more uniform. One type, with a particle size between 100 and 200 mesh, separates materials with appreciably different chemical properties by a combination of ion exchange and adsorption. A second type has a particle size that passes 200 mesh (dry), offers greater rate of reaction, and permits sharp separation of closely related chemicals.

A highly cross-linked polystyrene, sulfonic acid-type cation exchange resin (*Amberlite IR-124*, Rohm & Haas Co.) is designed to give longer operating life under strong oxidizing conditions. It is recommended for use in applications involving the treatment of solutions such as plating wastes, anodizing baths, etc.

A phenomenal growth in the field of ion exchange has taken place since the first synthetic organic exchange resins appeared on the chemical scene over twenty years ago. Today the synthetic organic resins have completely overshadowed the older types of inorganic exchangers.

The reasons for this development are the much wider variety of exchange groups that can be introduced into the organic resins, the possibility of obtaining, at will, differing degrees of porosity, and the greater chemical and physical stability of the organic exchangers under extremes of acidity and alkalinity.

Ion exchange resins may be classified as cation exchangers with either strongly or weakly acidic functional groups and anion exchangers which contain either strongly or weakly basic functional groups.

* Rohm & Haas Co., Washington Sq., Philadelphia, Pa.

Recent Developments and References were prepared by the editors.

Ion exchange reactions

The important reactions of these resins are shown in the schematic equations in Fig. 1, p. 125, in which "R" represents the insoluble organic resin skeleton to which the hydrophilic functional groups are attached.

All of the many types shown are capable of entering into the neutralization reaction, but this reaction is reversible by hydrolysis in the case of the weak acid or weak base resins. Second, all of the resins will exchange ions of one species for others of the same species, excepting the special cases of hydrogen and hydroxide ions. The reversibility of these reactions by means of changing the concentration of the solution contacting the resin is, of course, the feature that permits the economical employment of these materials in so many processes. Third, only the strong acid and base exchangers can "split neutral salts," liberating in the one case a strong acid, in the other case setting free a strong alkali.

There are several other fundamental chemical properties that are not revealed by the schematic equations that are listed in Fig. 1.

For example, ion exchange resins generally show different affinity for adsorbing different ions. Thus, for cation exchangers, ions of higher valence tend to replace ions of lower valence ($Th^{++++} > Al^{+++} > Ca^{++} > Na^{+}$) and ions of higher atomic number tend to replace ions of lower atomic number ($Cs^{+} > Rb^{+} > K^{+} > Na^{+} > Li^{+}$).

Another important property of ion exchange resins is their porosity. In order to make full use of all of the functional groups in a resin particle, it is obviously necessary to have pores large enough to permit the ions to diffuse into them.

The regular grades of ion exchange resins are sufficiently porous to admit all the ordinary inorganic ions. But there are certain applications involving large organic ions that require resins of unusually high porosity. The question of the means by which porosity may be controlled leads logically to a consideration of the methods of manufacture by which current resin types are produced.

Manufacture

The most important of the present-day ion exchange resins are made by copolymerizing styrene with a cross-linking agent such as divinylbenzene (DVB) and subsequently reacting this skeleton with agents that will introduce the desired functional groups, or by copolymerizing compounds already containing functional groups with cross-linking agents. Examples of the first procedure are sulfonation of the styrene DVB skeleton to yield

cation exchangers or chloromethylation followed by amination to yield anion exchangers. Examples of the second procedure are copolymerization of methacrylic acid with DVB or of maleic anhydride and styrene with DVB to yield weak acid cation exchangers.

There are still on the market today some very important ion exchange resins which are based on phenol-formaldehyde, aminobenzene-formaldehyde, or nitrogen heterocycle-formaldehyde condensates.

In all cases, control of the degree of porosity is possible. With the vinyl polymers, this is accomplished by regulating the amount of cross-linking agent; with the condensates, by the amount of formaldehyde used, or inert extenders can be added to both.

Still another important consideration with ion exchange resins is particle size and size distribution since these affect the rate of exchange and the hydraulic properties of the system. The vinyl copolymers are advantageously prepared by suspension polymerization which permits control of particle size. The condensation products are usually prepared in bulk and subsequently ground and sieved to the desired sizes.

Equipment and operation

By far the most general use of ion exchange resins is in column operation. That is to say, the resins are employed as fixed beds in suitable containers and are contacted by the solution that is to be treated as it flows through the bed.

After the resin has adsorbed all of the ions that it is capable of adsorbing under the conditions employed, it is regenerated by passing through the bed a more concentrated solution of a reagent that will return it to its original ionic form. Ion exchange processes are carried out on a laboratory scale in pipets, burettes, or small-diameter columns and on an industrial scale in tanks which are of sufficient size to hold several hundred cubic feet of ion exchange resin. Two other types of operation are being used in certain special instances.

A continuous ion exchange process is possible using moving beds of resin which are transferred by means of eductors from the exhausting chamber and recycled but this is a complex and expensive operation.

The other kind of operation is batchwise. In certain ore-treating processes, baskets of large particle size resin are dipped into slurries (or pulps) of the finely divided ore suspended in a leaching solution until the resin is saturated with the desired ion. The baskets are then removed and regenerated in another batchwise step. This batch-type operation is generally referred to as the resin-in-pulp process.

Applications

The largest amounts of ion exchange resins are currently being used in water conditioning.

There are two important processes in this field: 1) softening, i.e., the exchange of sodium for calcium and magnesium ions using cation exchangers; and 2) deionization, i.e., the removal of all ions using both cation and anion exchangers, either successively in two separate beds or simultaneously in a Monobed (mixed bed). Strong base resins in the hydroxide form will remove even silica, and highly porous strong base resins will remove organic matter, so that water of extremely high purity can be produced by means of these exchangers.

Other applications in the fields of waste treatment, metal recovery, food processing, analysis, industrial processes, catalysis, and so on, have been described in reference works and reviews.

Uranium recovery

Ion exchange resins are also indispensable in the recovery of uranium from ores in which it occurs in very low concentrations. These ores are leached with sulfuric acid or sodium carbonate solutions to produce a very dilute solution of complexed uranium anions which can be separated by conventional methods only with great difficulty. However, adsorption of the anion complex, such as $UO_2(SO_4)3^{-4}$ or $UO_2(CO_3)3^{-4}$, on strongly basic anion exchangers in the sulfate form and subsequent elution with nitrate or chloride solutions results in 50- to 100-fold concentration of the uranium originally present in the leach liquor. Precipitation processes can now be used to recover the uranium from the concentrated solution.

Certain uranium-bearing ores upon leaching produce slurries that are difficult to filter and hence unsuitable for passage through ion exchange columns. In order to recover the uranium from such liquors, an adsorption system, mentioned earlier, known as the resin-in-pulp method, is employed. In this system, baskets containing large particle size ion exchange resins are contacted with the slurry by mechanical agitators and the resin eluted after sufficient adsorption has occurred. Various schemes for continuous columnar ion exchange are also under development for the recovery of uranium. By the above techniques, at least 99% of the uranium in the leach liquors can be recovered as a concentrate having a U_3O_8 content greater than 70 percent.

Sugar refining

Rising standards of quality in crystalline and liquid sugars in this country have given impetus to the interest in ion exchange resins for the refining of sugar. Because of their ability to remove both ash and color bodies from sugar sirups, ion exchange resins can improve in striking fashion the final quality of liquid or crystalline sugars.

Raw cane sugar is generally put through the following refining steps: a water wash to remove molasses clinging to the crystals; solution in water followed by treatment with lime and phosphoric acid; filtration and passage through bone char and/or vegetable carbon. Several batches of white crystalline sugar can then be obtained from the sirup before the mother liquor must be returned to the refining cycle. The use of a highly porous strong base anion exchanger in the chloride form following a vegetable-carbon treatment removes additional color and sulfate ions, making it possible to obtain one or two extra crystallizations of white sugar. A smaller than nor-

mal quantity of vegetable carbon may be used and more expensive bone char completely eliminated. The resin is regenerated, for the most part, simply with salt, although occasional treatments with sodium hypochlorite to remove adsorbed color bodies are also employed. The extra "strikes" of crystalline sugar thus obtained and the savings in initial cost of bone char and rejuvenation steps required when the bone char is exhausted are very important to the sugar refiner.

In the production of liquid sugars, there is, of course, no crystallization step and it is necessary to use a mixed cation and anion exchange resin bed to de-ionize as well as to decolorize the sirup. The resins to be used in the de-ionization of the sirup depend on the type of sirup desired, whether sucrose or invert. If the latter is desired, a strongly acidic cation exchange resin in the hydrogen form together with a porous strongly basic anion exchanger is used in the mixed bed. If inversion is to be avoided, as in the case of production of sucrose sirup, a weakly acidic cation exchange resin is used instead of the strongly acidic resin.

Exchange resins are also used to refine dextrose and beet sugar.

Strong acid cation exchanger

Neutralization

$$RSO_3H + Na^+ + OH^- \rightarrow RSO_3Na + H_2O$$

Cation exchange

$$2\ RSO_3Na + Ca^{++} + 2\ Cl^- \leftrightharpoons (RSO_3)_2Ca + 2\ Na^+ + 2\ Cl^-$$

Neutral salt splitting

$$RSO_3H + Na^+ + Cl^- \leftrightharpoons RSO_3Na + H^+ + Cl^-$$

Weak acid cation exchanger

Neutralization

$$RCOOH + Na^+ + OH^- \leftrightharpoons RCOONa + H_2O$$

Cation exchange

$$2\ RCOONa + Ca^{++} + 2\ Cl^- \leftrightharpoons (RCOO)_2Ca + 2\ Na^+ + 2\ Cl^-$$

Neutral salt splitting

$$RCOOH + Na^+ + Cl^- \rightarrow \text{Virtually no reaction.}$$

Strong base anion exchanger

Neutralization

$$RN^+(CH_3)_3OH^- + H^+ + Cl^- \rightarrow RN^+(CH_3)_3Cl^- + H_2O$$

Anion exchange

$$RN^+(CH_3)_3Cl^- + 2Na^+ + SO_4^= \leftrightharpoons [RN^+(CH_3)_3]_2SO_4^= + 2Na^+ + 2Cl^-$$

Neutral salt splitting

$$RN^+(CH_3)_3OH^- + Na^+ + Cl^- \leftrightharpoons RN^+(CH_3)_3Cl^- + Na^+ + OH^-$$

Weak base anion exchangers

Neutralization

$$RN^+H_3OH^- + H^+ + Cl^- \leftrightharpoons RN^+H_3Cl^- + H_2O$$

Anion exchange

$$2RN^+H_3Cl^- + 2\ Na^+ + SO_4^= \leftrightharpoons (RN^+H_3)_2SO_4^= + 2\ Na^+ + 2\ Cl^-$$

Neutral salt splitting

$$RN^+H_3OH^- + Na^+ + Cl^- \rightarrow \text{Virtually no reaction.}$$

Fig. 1: Schematic equations of some important ion exchange resin reactions

Pharmaceutical

Powdered ion exchange resins are used in therapeutic oral and topical drug preparations. Weakly basic anion resins are available in the form of tablets, powders, or suspensions for use in ulcer therapy and as antacids. A weakly acidic carboxylic cation resin gained widespread importance as an effective means of controlling cardiac edema through sodium reduction. More recently, sustained release oral compounds, employing various ion exchange resins as carriers for such drugs as *p*-aminosalicylic acid, amphetamine, etc., have been introduced. In many instances, the use of exchange resins as carriers provides a means of lowering the threshold of irritation of certain drugs which produce undesirable side reactions when administered in their free form.

A micropowdered exchange resin or combination of resins can be used in skin creams, lotions, and powders as a means of maintaining the natural acid mantle factor of the human skin and normal skin health. The strong absorption affinity of exchange resins for low-molecular-weight fatty acids and protein degradation products has stimulated interest in the development of antiperspirant-deodorant preparations employing small concentrations of exchange resins. Clinical evidence indicates advantages in lack of irritation as well as longer protection.

Isocyanate Resins

BY J. H. SAUNDERS* and R. C. BURCK**

RECENT DEVELOPMENTS

A polyaryl polyisocyanate (*Papi*, Carwin Co.), is expected to find extensive use in increasing the resiliency and raising the heat distortion point of flexible and rigid urethane foams. An *n*-butyl isocyanate (*Bunco*, Carwin Co.) is expected to find application in various phases of the textile field, such as waterproofing fabrics, increasing wear resistance of wool, and in tanning hides.

Flexible urethane foams are now being prepared from diisocyanates and polypropylene glycols of several types. The new foams have three main advantages over conventional diisocyanate-polyester foams: they can be more readily molded; they can be made in much softer grades; and they have better resistance to accelerated aging conditions of combined heat and high humidity. These improvements in properties should greatly expand present markets and should bring urethane foams into many new fields of application.

A new polyisocyanate has been developed to overcome one of the principal limitations to the use of urethane coatings. Most urethane coatings were previously based on formulations containing some free tolylene diisocyanate, which is a respiratory irritant. The new polyisocyanate (*Mondur CB*, Mobay Chemical Co.) contains less than 1% of free tolylene diisocyanate, and consequently can be handled much more freely than previous related materials.

Much better temperature resistance than was previously possible with urethane wire enamels has resulted from the combination of a new disguised or blocked polyisocyanate and a new polyester (*Mondur SH* and *Multron F-38*, respectively, Mobay Chemical Co.). While the enamel based on these materials is not readily solderable, it is expected to find use in many applications for which performance in the 150 to 180° C. range is desired.

A magnet wire insulation material for use on solderable wire is based on a combination of polyvinyl formal (*Formvar*, Shawinigan Resins Corp.) and urethane. This combination gives exceptional coatings with respect to solderability at low temperatures, resistance to thermoplastic flow, low extractible content, and resistance to softening by refrigerant Freon 22.

Isothane polyurethane stripper (Surface Chemicals, Inc.), a noncorrosive solvent-type stripper, has been developed to promote the removal of polyurethane reaction products from ferrous and nonferrous metals. Applied by dip, flow coat, brush, or spray, its action is complete after a short contact period. Simple solvent wash after stripping will give recoatable surfaces.

Isocyanate resins, also known as "polyurethane" or simply "urethane" resins, are an outgrowth of research in Germany and in the United States since 1937. They have approached commercial production here only within the past year. The major fields of use include flexible and rigid foams and coatings; adhesives and synthetic elastomers are still in the development stage, but show great promise.

The isocyanates of greatest commercial importance are the diisocyanates; of these, tolylene diisocyanate is most widely used. A variety of compounds containing two or more "active hydrogen" groups, e.g., hydroxyl, amino, and carboxyl, may be used to react with the diisocyanates to produce polymers. The most widely investigated compounds for reaction with diisocyanates, and the principal ones used on a commercial scale at this time, are the polyesters. These polyesters are generally liquids of moderate molecular weight, e.g., 1000 to 2500, and terminate principally in hydroxyl groups. The polyesters vary greatly in their degree of branching, the desired final polymer properties determining the degree of branching used. Linear polyesters usually lead to elastic polyurethanes, whereas highly branched polyesters give rigid polyurethanes. Essentially any degree of rigidity or flexibility may be obtained by the proper choice of reactants.

Chemistry

In reacting with the polyesters, the diisocyanates $[R(NCO)_2]$ combine with hydroxyl groups in the polyester $[R'(OH)_2]$, joining polyester molecules together with urethane linkages as shown in Formula 1, p. 127.

For applications in which films, solid plastics, or solid elastomers are desired, this is the principal reaction. However, when a foam is desired, an excess of diisocyanate and water are added. In this case the diisocyanate serves both as a cross-linking agent and as a blowing agent. The reaction with water furnishes the gas for foaming, as is illustrated for a monoisocyanate below:

$$2\ RNCO + H_2O \rightarrow RNHCONHR + CO_2$$

In addition to the polyesters, simple glycols, polyethers, castor oil, drying oils, and a host of other polyfunctional materials have been treated with diisocyanates to prepare useful products. Monoisocyanates have also been

* Assistant Director, Research Dept., Mobay Chemical Co., New Martinsville, W. Va.
** Development Dept., Mobay Chemical Co., 1900 S. 2 St., St. Louis, Mo.
Recent Developments and References were prepared by the editors.

used for a variety of applications, including waterproofing textiles and leather, and as chemical intermediates in the drug industry.

Foams

Development of soft, flexible, and rigid urethane foams has continued at an accelerated rate.

These urethane foams, whether flexible or rigid, most often are prepared commercially from polyesters, diisocyanates, and water. The mechanical characteristics of the foam depend largely on the choice of polyester. By varying the degree of branching, either flexible or rigid foams can be prepared. The diisocyanate reacts with the polyester, converting that low-molecular-weight liquid polymer into a high-molecular-weight elastomer or plastic. At the same time the diisocyanate reacts with water to generate carbon dioxide, which foams the resin. The density of the foam is controlled by the amount of water and the corresponding amount of diisocyanate used.

In addition to these major ingredients, other agents such as catalysts and emulsifiers may be added to control the rate of foaming and the cell structure of the foam. All ingredients may be mixed at one time, using good agitation. Just as the evolution of gas begins, the liquid mixture is poured into the mold or cavity to be filled, and the foaming reaction will proceed without the application of heat or pressure. The foaming recipe must be carefully adjusted to provide gas evolution at a suitable rate and before gelation occurs. The time and degree of mixing of the ingredients must be closely controlled. The preparation of flexible foams requires 25 to 50 parts of diisocyanate per 100 parts of polyester, while rigid foams usually require 60 to 100 parts of diisocyanate. Lighter foams of either type require more diisocyanate than do the denser foams.

Two-component systems are available for hand mixing in the field, but most production involves the simultaneous machine mixing of all ingredients immediately before foaming. One of the most important developments in the field of urethane foams is the design of suitable machinery for the continuous production of foam of outstanding quality and uniformity of structure. Blocks of flexible foam up to 80 in. wide, 25 ft. long, and 10 in. high are being produced. Spray-gun type and intermittent foaming equipment are also being developed.

An outstanding advantage of the urethane foams is that they can be "foamed in place" without the application of heat or pressure. The foam rises, completely filling irregular cavities, and bonding well to the walls of the container. The foaming reactions are exothermic and of sufficient driving force to complete the curing of the foam. This advantage is of special value in the use of rigid foams for structural and insulation purposes, where great savings in labor may be realized. It also is useful in the foaming of shaped articles in molds, using flexible or rigid foams.

$$R(NCO)_2 + R'(OH)_2 \rightarrow \left[R\text{–}NHCO\text{–}R'\text{–}OCNH \right]_x$$

Formula 1: Polyester molecules joined together with urethane linkages

Flexible foams having a predominantly open-cell structure are available in a density range of 2 to 6 lb./cu. foot. Foam may be prepared in a variety of colors, and may easily be produced so that it will not support combustion. Mechanical properties are such that a 2.5 lb./cu. ft. urethane foam (see Table I, p. 128) is superior to a medium-density latex foam in load-bearing characteristics and tensile strength.

The combination of properties shown makes flexible urethane foam excellent for cushioning uses. The flame-resistant characteristics make it especially attractive for use in public meeting places, transportation vehicles, and hotels. The high tensile strength and tear- and abrasion-resistance are very desirable for such uses as toys, sponges, and gaskets. Its open-cell structure and good sound absorption, flame resistance, and the ease with which it is spray-painted forecast its use for acoustical insulation.

Rigid urethane foams are available in a density range of 2 to 30 lb./cu. ft., and have predominantly closed cells. A variety of rigid foams are available having different mechanical properties. Compression and tensile strength of typical rigid foams are shown in Table II, p. 128.

In addition, the adhesion to container walls, and impact and vibration resistance of rigid foams are excellent. The dielectric properties, chemical resistance, and thermal conductivity properties are good. The maximum temperature for use is high, 150° C. for a standard 12 lb./cu. ft. foam.

These properties of the rigid foams make them attractive for applications requiring simplicity of processing equipment, good mechanical strength, temperature and vibration resistance, and closed-cell structure. These products have been used extensively in the aircraft industry for filling cavities in radomes, ailerons, rudders, elevators, wing tabs, and for insulating cabin ventilating systems. Other uses of importance include the construction of nonsinkable boats and pontoons. Applications in the field of insulation, as in houses and refrigerators, are being explored.

Coatings

Urethane coatings are now being used on a commercial scale in applications where the combination of their unusual properties has made them immediately acceptable. They are formulated with partially reacted isocyanates (adducts) and are used both in one- and two-component systems. The one-component coatings are made with a "blocked" isocyanate and at room temperature are stable; at elevated (bake) temperatures the blocking agent is

TABLE I: Mechanical properties of a typical 2.5 lb./cu. ft. flexible urethane foam

Property	*Value*
Indentation strength, 25% indentation, lb./50 sq. in.	10-60
Compression set, 158°F., maximum[1] %	5-10
Tensile strength, p.s.i.	15-30
Tear strength, lb./in.	4-6
Elongation, %	180-300

[1]Based on original height.

driven off and the isocyanate is available for reaction. Two-component systems have a practical work or container life of 24 to 48 hr. after mixing, and this can be extended still further by certain storage and mixing procedures; they will cure at room temperature but can be accelerated by use of heat. Like urethane foams, the chemical and physical properties of the coatings are dependent to a large degree on the choice of polyester.

Both the clear and pigmented urethane coatings produce hard, high-gloss surfaces in an air-dry system. They develop excellent adhesion to almost all surfaces. The extensive use of these coatings in Europe has shown them to have good abrasion- and impact-resistance as well as chemical, solvent, fresh and salt water, and moisture resistances, and good weathering properties. Use in this country has confirmed their excellent dielectric properties.

Elastomers

Similar to the flexible foams, solid elastomers are being prepared from linear polyesters and an excess of diisocyanate. Unlike the foams, however, the elastomers are usually prepared without catalysts and emulsifiers, and only a low concentration of water, if any, is used. Some agent such as water, a glycol, an amino alcohol, or a diamine is used in small amounts to insure adequate urethane or urea groups, which are potential points for cross-linking with the excess of diisocyanate.

Two different techniques are used for preparing the elastomers. In one—the "casting process"—all ingredients are mixed within a very short time, and the liquid mixture is poured into a mold and cured. In the other—using a "storage stable" intermediate elastomer—a material somewhat resembling raw rubber is prepared, using an amount of diisocyanate that is insufficient for complete cure. The product thus formed is stable, and can be cured by treatment with more diisocyanate.

The isocyanate-polyester rubbers have outstanding abrasion- and tear-resistance, as well as excellent tensile strength, ozone resistance, and oil resistance. They have moderate resistance to dry heat, but are limited in their resistance to extremes of temperature, hot water, acids, and alkalies. Like the other isocyanate products, these elastomers are available in a considerable range of hardness and other properties.

Appropriate grades of these elastomers are being used in Europe in applications such as solid tires, gears, conveyor belts, shoe heels, gaskets, handles for air hammers, pump linings, etc. Investigations in this country have been directed more toward use in car tires.

Adhesives

Isocyanate resins have been used quite extensively in formulating adhesives for the rubber industry. Used by themselves and as additives to rubber-based adhesives, the isocyanates promote excellent adhesion to both metallic and nonmetallic surfaces.

The principles described in the preparation of urethane coatings can also be applied to urethane adhesives.

Natural Resins

The natural resins constitute a continuous series of solid, nontoxic, film-forming gums varying over a broad range of solubilities and hardness. Named for their source of origin, in most cases, they are classified into four major groups, as follows: 1) Damars; 2) East Indias: batu, black, pale; 3) Copals: manila, pontianak, kauri, congo; and 4) Miscellaneous: accroides, elemi, mastic, sandarac.

Almost all of the natural resins are simply cold-cut in solvents where they are generally compatible with substances soluble in the same materials. Many of the resins are oil-soluble in their raw state, while others (congo, black and pale East Indias, kauri) are prerun at high heats. A range of grades is available in all of the varieties.

Damars are versatile resins, having adhesion, depth of gloss, color, gloss retention, miscibility, and resistance to scuffing, greases, and cold checking. "Dewaxed" Damar is a lacquer resin.

East Indias are related to the Damars. Batu is a high-melting-point resin with greater viscosity, water resistance, and weather resistance. It has fast solvent release, and compatibility with stearic acid and a wide range of oils, waxes, resins, asphalts, pitches, chlorinated rubber, and cellulose derivatives. Uses include varnishes, inks, adhesives, and composition products. Black East India makes an opaque varnish that dries to a light color. It provides tough varnishes for metals and wood with water resistance, adhesion, and flexibility. Pale East India yields greater control of sheen. Its resistance to temperature changes and water makes it useful in special-purpose varnishes.

Copals: Manilas are broadly used in alcohol solutions for varnishes, printing inks, adhesives, liquid waxes, compositions, and specialty products; gloss, color retention, and flexibility give it broad usage. *Pontianak* is similar to the manilas but of higher melting point. *Kauri* has long been used as a basic varnish resin. Certain grades are alcohol-soluble. This is a fossil resin. *Congo* is insoluble in its original state. Processed, it can be adapted to broad uses in varnish coatings in which toughness, flexibility, adhesion, color, and gloss retention are desired. Metal coatings, floor varnishes, enamels, wrinkle finishes, and furniture varnishes are some of its outlets.

Accroides (red, yacca) is a specialty resin with thermosetting qualities. Its red color is inseparable. *Elemi* is a plasticizing resin used in varnishes, lacquers, caulking compounds, and specialty coatings. *Mastic* and *sandarac* are specialty resins used in artistic fields.

Amber: This yellowish, transparent-to-translucent, fossil resin is derived from an extinct conifer. It takes a polish well and is the hardest known natural resin. However, it is brittle and breaks with a conchordal fracture.

Shellac: This natural resin is produced by tree lice *(Tacoardia lacca)* found in Asia. Shellac exhibits characteristics of both thermoplastic and thermosetting types of binders, retaining its thermoplasticity for a long period when heated. Heat-curing increases the mechanical and electrical strength of the material.

Rosin: This product of pine tree exudations consists largely of abietic acid, together with other complex terpenic acids and esters. It has not been used extensively in molding compositions because of its low softening point and brittleness.

Vinsol[1] is another product of the steam distillation process by which naval stores are extracted from the wood of the long-leaf Southern pine. It is an ideal modifier for most natural and synthetic resins. High-melting materials or thermosetting condensates are produced by reacting the resin with aldehydes. It is soluble in alcohols, esters, cyclic hydrocarbons, and chlorinated solvents, possesses high dielectric strength, a low power factor even at high temperatures, and has the ability to withstand high-voltage electrical impulses.

[1] Trademark of Hercules Powder Co.

Asphalts: These are naturally-occurring hydrocarbon complexes, termed bitumens, which are insoluble in water, but soluble in carbon disulfide and benzene. The amorphous brownish to black mixtures range from mobile fluids to hard friable solids. Asphalts can also be processed to yield products with a wide range of physical properties such as good dielectric properties and resistance to moisture, acid, alkali, and most chemicals.

Cashew resins: The cashew nut is obtained mainly from India. The heat-reactive-type resins formed by condensation of the cashew phenols with aldehydes are available in the form of mobile liquids, viscous liquids, powdered fusible solids, granular infusible solids, and rubbery infusible solids. Typical applications for these cashew nutshell liquid resins are adhesives, phenolic resin plasticizers, potting compounds, protective coatings, rubber compounding, and synthetic drying oils of an extreme degree of alkali resistance; they also find use in automotive and other brake linings.

Nylons (Polyamides)

RECENT DEVELOPMENTS

A new nylon resin (*Zytel 42*, Du Pont) has a viscosity tailored for use in extrusion equipment. Its applications include tubing for an automobile lubrication network which the motorist can actuate by pushing a button; as an actuator rod moving inside a retractable auto radio antenna; washers; aircraft grommets; and bearings. The material has also been blow molded to produce aerosol containers.

An improved polycaprolactam-type nylon (*Plaskon Nylon 8201*, Barrett Div., Allied Chemical & Dye Corp.) extends the range of products fabricated from nylon, particularly clear film and small-diameter tubing and rod. The new material is characterized by its low moisture content, wide range of permissible stock temperatures, and relatively high molten viscosity, resulting in improved moldability and extrusion, lower processing temperature, minimized shrinkage in thick sections, and elimination of voids.

Molybdenum disulfide-filled nylon thrust washers (*Nylatron GS*, The Polymer Corp. of Pennsylvania) are used where good wear resistance under light thrust conditions is required. The filled nylon formulation has better dimensional stability and lower deformation under load than standard nylon, coupled with a lower coefficient of friction and higher wear resistance.

Nylon pipe (*Tempertube*, The Danielson Mfg. Co.) is claimed to provide greater bursting strength and higher heat resistance than other plastics pipe of comparable dimensions. The pipe is supplied in straight lengths or continuous coils in sizes from ⅜ to 1½ in. O.D. with wall thicknesses from 0.025 to 0.125 inch.

An epoxy-based compound (*Bonding Agent R-323*, Carl H. Biggs Co.) designed to bond nylon to itself, to metal, or to other materials possesses high bond and peel strength. It may also be used with rubber.

Extruded blown-flat nylon tubing and heat-sealed bags are being produced from type 6 nylon (Kemtek Corp.). The film withstands either steam or dry sterilization in an autoclave with no loss of physical properties, resists most solvents, and is sealable by heat or high frequency. It resists the passage of oxygen and other gases and liquids, while allowing slight transfer of water vapor.

Nylons are polymeric resins, formed by the condensation of dibasic organic acids with diamines into linear chains containing amide groups. They were developed in the classic researches of W. H. Carothers and introduced on the market in 1938 in the form of bristles and hosiery fibers. The inherent properties of the materials, however, such as strength, toughness, ability to withstand high temperatures, abrasion resistance, and good chemical resistance made it quickly apparent that a potential existed as an industrial molding powder. Consumption of nylon powders for this purpose has increased considerably over the past few years.

Table I, p. 132, lists the various types of present-day commercial nylons, showing the chemical raw materials used to make them and the properties that are imparted by them to the different nylons listed.

This article is based on information supplied by E. I. du Pont de Nemours & Co., Inc.; Spencer Chemical Co.; Barrett Div., Allied Chemical & Dye Corp.; Foster Grant Co., Inc.; and The Polymer Corp. of Pa.

Properties

Within the wide range of nylons available, the three most important types of nylon are nylon 6/6, nylon 6, and nylon 6/10. Nylon 6/6 (so-called because both the acid and amine used in making it contain 6 carbon atoms) is the most common and oldest type of nylon. Nylon 6, a newer material, is a polymer made by opening the ring of caprolactam, a 6-carbon condensed amide, and reportedly has a higher impact strength, is easier to mold, and more flexible than nylon 6/6. Nylon 6/6, however, is harder, has greater abrasion and heat resistance, and shorter molding cycles.

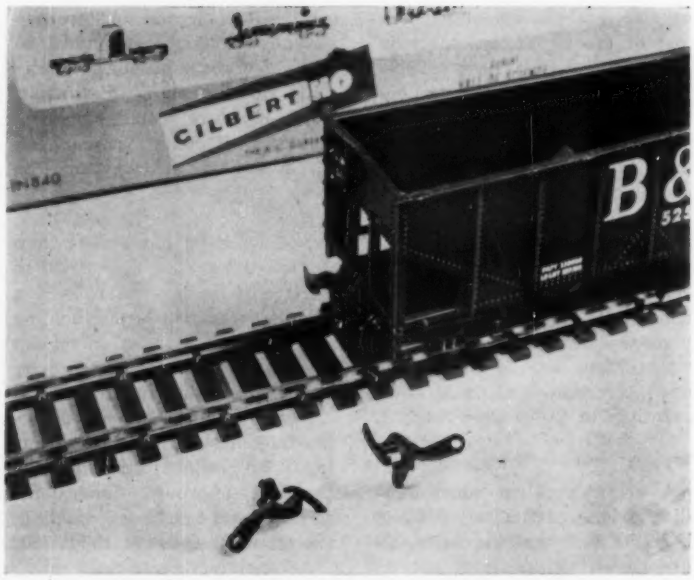
In the manufacture of the third major type of nylon, 6/10, sebacic acid is substituted for the adipic acid component to yield a softer, tougher, more resilient polymer with lower water absorption.

Over-all, however, the common 6/6 and 6 nylons have fitted into their important and rapidly growing uses because of a unique combination of desirable properties. They are stiff, strong, tough, light, abrasion-resistant, and self-extinguishing, have a low coefficient of friction, and are chemically and thermally resistant. Such properties, plus their ability to be accurately molded into intricate shapes, have fitted them for mechanical and other critical applications where they either replace less satisfactory or more expensive metal parts or do jobs previously not possible. While wear properties are improved by lubrication, nylon moldings give excellent service with no lubrication under many service conditions and will frequently outwear corresponding metal parts. Nylon's chemical resistance is particularly valuable where electrolytic action corrodes metal parts, particularly where a bimetallic junction is involved. Various marine and oilfield uses capitalize on this property.

Research work has also been going forward on various types of reinforced nylon molding compounds. One manufacturer claims

to have developed a glass fiber-filled nylon with tensile strengths much greater than nylon in its virgin state. Another manufacturer reports on a molybdenum disulfide-filled nylon which offers high wear resistance, low dry running friction, and excellent dimensional stability.

Processing nylon



Injection molding and extrusion are the usual methods of processing nylon; application from solution, compression molding, sintering, and other techniques are used for special purposes.

The common nylon 6/6 and 6 compounds can all be handled in conventional machines with little modification in equipment or procedures. When injection molding nylon 6/6, what differences do exist can be attributed largely to the material's sharp melting point and low melt viscosity. This makes it necessary to fill molds as quickly as possible and the use of a booster is usually recommended. Nylon 6/6 also tends to freeze rapidly, contributing to rapid cycle and minimizing flash problems.

According to manufacturers of nylon 6, the material has a higher melt viscosity and a wider molten range than 6/6 nylon,[1] making it possible to mold parts having larger surface areas or thick cross-sections. Since the material does not solidify as quickly as other nylons, the sink marks and internal voids and cavities that might appear in heavier or thicker pieces are avoided. Manufacturers also claim that nylon 6 has a wider temperature working range (loosely defined as the temperature between which a resin becomes fluid and the temperature at which the resin undergoes temperature degradation) and that crystallinity which determines the degree of transparency or opacity can be more closely controlled.

In extrusion-grade materials, both nylon 6/6 (e.g., Zytel 42[2]) and nylon 6 are available with higher melt viscosities than were heretofore possible—and consequently extruded nylon profiles, tubing, pipe, film, and sheeting have started to find important new markets. Considerable activity has been noted in developing the use of nylon pipe in applications where the superior chemical resistance and heat resistance of the nylons is indicated. Extruded tubing has also made a place for itself in applications, e.g., pressure lubricating systems, where resistance to pressure and vibration combined with oil resistance are important. Extruded film and sheet is at present in the development stage but should shortly be made available for packaging and other fields.

Molybdenumdisulfide-filled nylon was used for 11 parts of fuel pump because of better molding properties and higher wear resistance. (Photo, National Polymer)

[1] The extrusion-grade nylon 6/6s, however, are available with much higher melt viscosities than are available with the molding-grade nylon 6/6. See text, above.
[2] Trademark of E. I. du Pont de Nemours & Co., Inc.

can also easily be machined. This type of fabrication is especially recommended for symmetrical components with multiple undercuts, internal threads, and longer inside diameters. The break-even point between molding or machining nylon parts is generally higher for smaller parts. For example, results on a part with a volume of 0.7 cu. in. indicate it would be more economical to mold than screw machine in quantities of 2000 and up, while a part 0.1 cu. in. did not become more economical to mold until quantities of 40,000 were reached.

Drying

A major problem when handling nylons, particularly 6/6 and 6, is the fact that the materials are hygroscopic and will eventually absorb about 2½% moisture under average atmospheric conditions. However, more than about 0.3% moisture causes splayed moldings of reduced toughness. Therefore, every effort should be made to protect the molding powder from atmospheric moisture. If excess moisture has been picked up, the nylon should be dried in a circulating-air oven or a vacuum oven before the molding operation. It is most important that the air taken in by the drier be low in relative humidity.

Several after-treatments of nylon moldings are used to advantage. To relieve stresses, and thereby improve dimensional stability and toughness, moldings are often annealed at about 350° F. in an inert medium such as Glyco-wax S932. Furthermore, since 6/6 and 6 nylon, as mentioned above, will absorb about 2½% moisture under normal atmospheric conditions, it is often convenient to add about this much water by immersing in boiling water in order to improve the toughness of the molded piece.

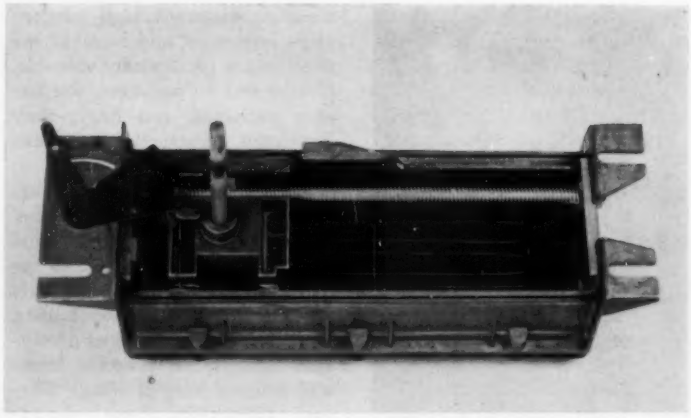
Applications[3]

Nylon is more often used because of its combination of excellent properties than for any one single characteristic. These various properties have been exploited by a constantly expanding family of applications. The 6/6 and 6 nylons are particularly

[3] This section based on information supplied by L. T. Sherwood, Polychemicals Dept., E. I. du Pont de Nemours & Co., Inc.

TABLE I: The nylons—raw materials, tradenames, properties

Chemical basis of nylon	*Common designation*	*Suppliers and tradenames*	*Comments on properties*
Hexamethylene-diamine-adipic acid	nylon-6/6	E. I. du Pont de Nemours and Co., Inc.—Zytel 42, 101, and 105	Zytel 42 is an extrusion-grade material with higher melt viscosity. Zytel 101 is a general-purpose material. Zytel 105 is same with carbon black added for weather resistance.
Hexamethylene-diamine-sebacic acid	nylon-6/10	E. I. du Pont de Nemours and Co., Inc.—Zytel 31 and 33	More moisture resistant than the above, more flexible, easier to work, less heat resistant, and less stiff. Zytel 33 is heat-stabilized Zytel 31.
Alkoxy-substituted nylon, hexamethylene-adipic acid		Belding-Corficelli Industries—B.C.I. Nylon	For fiber bonding and treating, extrusion, and solution-coating. By heat and/or acid can be cross-linked and made thermoset. Soluble when thermoplastic.
Not disclosed, possibly a copolymer		E. I. du Pont de Nemours and Co., Inc.—Zytel 63 and 69	Soluble in methanol and ethanol, but cannot be made insoluble. Used chiefly for textile treating.
Not disclosed, made specifically for the army		E. I. du Pont de Nemours and Co., Inc.—Zytel 3606	Made only to army specifications for infantry wire jacket.
Polycaprolactam	nylon-6	Barrett Div., Allied Chemical and Dye Corp.—Plaskon Nylon 8200 and 8201 E. I. du Pont de Nemours and Co., Inc.—Zytel 211 Spencer Chemical Co.—Spencer Nylon 401, 402, 600, 601, 602, 603, 604, and 606. Foster Grant Co., Inc.—Fostylon Alfred C. Toepfer, Inc.—Grilon American Enka Corp.—Nylenka	Controllable crystalline structure, permitting orientation for film. Fairly high molten viscosity. Wider plasticizing range for molding larger pieces.
Polymer based on castor oil derivative, 11-amino andecanoic acid	nylon-11	Rilsan Corp.—Rilsan	Easily plasticized. Low specific gravity. Fairly low melt point but high decomposition point. Very fluid. May be graphited for friction applications. High moisture resistance.



useful in molded mechanical parts. For example, nylon gears and bushings are being used in textile machinery, household appliances, calculating equipment, automobile speedometers, and windshield wipers, and in office and builder's hardware, to mention only a few. In addition to its other properties, nylon's excellent abrasion resistance in the absence of lubrication is particularly valuable where frequent oiling is either undesirable or inconvenient. For example, lubrication adequate for metal parts is often very undesirable in textile and food machinery, while in household appliances and fishing reels, it is apt to be neglected by the ultimate user.

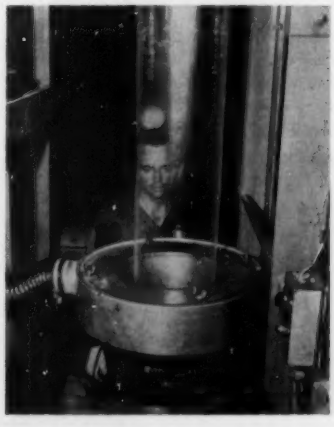
Other mechanical parts using nylon's frictional properties include elevator gibs and sliding parts for storm windows.

Another of nylon's properties, its impact resistance, is particularly valuable for automobile and refrigerator door-closing mechanisms, many housings, cams, and aerosol bottles. Two recent developments are expected to promote this latter market even further. One is the availability of resins designed for extrusion and blow molding and the second is the development of spin-sealing techniques. This technique makes it possible to injection mold a bottle in two halves and economically join them together by a spinning operation.

The strength and stiffness of nylon are required in almost all of its uses. Its retention of these properties at elevated temperatures gives it wide acceptance for coil forms. These have been produced in tremendous quantities—offering economies due to mass production and injection molding techniques and because breakage during winding is minimized. In mixer valves for automatic washing machines its mechanical properties and inertness to hot water combine to make it the choice of a large majority of appliance manufacturers.

Nylon's electrical properties are adequate for many other electrical applications where its mechanical properties are of prime importance. These include switch housings, grommets, cable clamps and other fastening devices, insulated connectors, and numerous other molded parts in this category.

Tuner assembly for automatic washer has nylon drive plate which triggers timing device and nylon control rod which activates cycle sequence. (Photo, G.E. Co.)



Nylon's chemical resistance is a determining factor in many applications. For example, marine equipment, aerosol valve parts, and moldings exposed to oil well brines must resist electrolytic corrosion. An outstanding new advance is the naval stuffing tube which is not only lighter and less expensive to produce than the conventional fittings, but also has excellent resistance to salt water corrosion.

Where long-term exposure to elevated temperatures (250° F.) is required, various heat-stabilized resins are available. Useful examples are electronic components and in fastening devices for the aircraft industry. Other resins for special purposes include the black weather-resistant nylons. These are suggested for use in agricultural machinery, sporting goods, electrical equipment, and for other applications where outdoor exposure is involved.

Extrusion applications for nylon are expected to account for an increasing share of the total business. Resins of viscosity suitable for molding may be used for simple extrusion operations where retention of shape is not critical. Here the low viscosity of many nylons above their melting points is not a handicap. However, where retention of shape after leaving an extruder die is important, as for blown bottles and any but the most simple shape extrusions, new high viscosity resins are now beginning to assume a more prominent place in the industry.

The use of nylon as a jacket for wire and cable is well established. In some cases, such as magnet wire and geophysical cable, it may be used as a primary insulant but it is more commonly used as a temperature- and abrasion-resistant jacketing over polyethylene, rubber, or vinyl compounds. Aircraft and other types of hookup wire, tree wire, and electric blanket wire are common examples. The softer grades of nylon are also used for control cable

Nylon-6 film, here being produced on standard equipment designed for polyethylene film, can be drawn down to 0.2 mil. (Photo, Spencer Chemical Co.)

Oil carrying can is assembled by heat-sealing two molded nylon-6 parts together. (Photo, Algemene Kunstzijde Unie, N.V.)

jackets, as in tiller cable for small boats and for various roll-up devices.

For outdoor applications, weather-resistant grades of extrusion resins have recently become available. These permit construction of highly abrasion-resistant wires with outdoor life comparable to the best materials.

The properties of nylon make it ideally suited for many tubing applications. Its strength, fatigue resistance, and chemical inertness, particularly to hydrocarbons, make it attractive for automotive and other lubrication systems, for fuel lines, air suspension systems, and many other applications. Its lightness and ease of assembly have made possible important economies in a great many installations.

Still other markets exist in films and laminates. Here the high abrasion resistance, high-temperature properties, and chemical resistance are particularly valuable. Grease and oil packages, sterilizable packages, and heavy-duty laminated constructions are examples.

A major potential market exists in the field of aerosol bottles. Here, strength, toughness, and impermeability contribute to the design of attractive bottles of almost unlimited color possibilities, with the added feature of protection against the possible losses and dangers from breakage. Several fabricators have already made production runs of nylon bottles and others are in the offing.

Less rigid and soluble types of nylon find many specialty uses. As moldings, they are useful where extremely high impact strength is required. Examples include soft-faced hammers and bowling pin bases. In the hammer application, prior to the selection of nylon, the manufacturer tested a wide range of materials by striking each one 140 times a minute with a sharp-pointed object giving a 50 ft.-lb. blow. Nylon lasted over 150 hr.—or approximately 1,260,000 blows—2½ times as long as the next best material. In addition, nylon offered several other advantages. It is dimensionally stable and the face of the hammer does not work loose from the ferrule in which it is seated. In addition, nylon does not mushroom or chip and gives an effective blow without bouncing or marring the work.

Applied as solutions or dispersions, the nylons form impermeable linings for aircraft fuel cells, and are widely used as soft, abrasion-resistant finishes for textiles, leather, and other products.

Injection molded nylon helmets take advantage of nylon's superior impact resistance and shock resistance. (Photo, J. Cerfontaine, Belgium)

Phenolics

BY A. P. LANDALL*

The history of phenolics dates back about fifty years to the time when Dr. L. H. Baekeland first announced the controlled phenol-formaldehyde resin reaction in 1909. The significance of Dr. Baekeland's work was the ability to control the phenol aldehyde reaction and his visualization of its commercial possibilities. Coincidental work in the field was carried out by Aylsworth and by Redman and his co-workers, Weith and Brock.

PHENOL-FORMALDEHYDE

The advantages the phenolics offer are many. With proper manufacture and application, phenolic is a strong, rigid, dimensionally stable material, resistant to heat and a wide variety of solvents, and, most important, a nonconductor of electricity. It is this last characteristic that has given the greatest impetus to the large-volume usage of phenolic materials.

Chemistry

Phenol and formaldehyde combine in the presence of a catalytic agent to produce phenolic resins. These phenolic resins can be classified broadly as either one-stage or two-stage resins.

When a mol ratio of 1:1 or greater of formaldehyde to phenol is used in combination with an alkaline catalyst such as caustic soda or ammonia, the reaction yields a *one-stage* resin which is called a resol in its initial stage. There are only four general types of reactions that are universally accepted as taking place under alkaline catalysis during resinification. These four reactions are capable of many combinations and permutations, which makes the study of this resin's technology extremely complex. The four basic reactions include: 1) methylolation; 2) condensation of two methylol groups to form an ether bridge; 3) condensation between a methylol group and a phenol nucleus to form a methylene bridge; and 4) decomposition of ether bridges to form methylene bridges and formaldehyde which immediately reacts via the first three reactions. These reactions are capable of taking place in any open ortho or para position in any phenolic nucleus no matter how large the methylolation. They can also result from the formation of a methylene bridge by condensation between a methylol group and a phenol nucleus in any open ortho or para position, no matter how large the polymer molecule may be.

Any methylol group present in the polymer may undergo a condensation of two methylol groups to form an ether bridge or condensation to form a methylene bridge. Any ether bridge in any phenolic polymer may be decomposed to form methylene bridges and formaldehyde and, of course, undergo further reaction.

The general procedures used are as follows:

In the manufacture of a one-stage resin all of the monomers needed for full polymerization are charged to the resin kettle at the start. The initial increase in viscosity because of the

Recent Developments and References were prepared by the editors.

RECENT DEVELOPMENTS

A new phenolic molding compound (*Resinox 2200 Black*, Monsanto Chemical Co.) combines excellent dimensional stability with high arc resistance and good impact strength. Formulated for use in heavy-duty electrical control parts and wiring devices, it is also well-suited for the manufacture of other parts requiring superior dimensional stability during temperature cycling, improved impact strength, and resistance to surface arcing.

A mineral-filled phenolic molding compound in nodular form (*RX-460*, Rogers Corp.) is intended for applications requiring greater strength than is usually found in heat-resistant materials suitable for automatic molding and preforming.

An ammonia-free, wood-flour-filled phenolic compound (*Durez 18441*, Durez Plastics Div., Hooker Electrochemical Co.) has been developed for use where a single-stage electrical-grade material of general-purpose type is required to minimize corrosion of electrical contacts and metal inserts. The compound has a very fast rate of cure, good finish characteristics, and low gravity. It is especially suitable for automatic compression, plunger, and transfer molding processes.

A medium-high impact molding compound (*RX-470*, Rogers Corp.) with cellulose filler is the highest impact material available in nodular form. It is preformable on automatic preforming equipment which is equipped with vibrating-feed hoppers and filling tubes of adequate cross-section area. According to the manufacturer, it has a fast rate of cure and molds with an excellent finish for a material of this impact class. The impact strength (ft.-lb./in. of notch) for a molded specimen is 1.50 (min.).

A new one-stage phenolic (*12902*, General Electric Co.) is designed specifically for molding in automatic presses. It offers fast cure rates, excellent release characteristics, low bulk factor, and uniform granulation. This manufac-

turer also announced two new improved general-purpose compounds (*12920 Black* and *12921 Brown*) with wider flow range, improved finish, longer flow duration, and faster cure and a new high-heat resistant phenolic molding powder (*G-E 12980*).

A heat-resistant, medium-impact phenolic (*HR-322*, Durite Dept., The Borden Co., Chemical Div.), which can be compression and plunger molded and preformed, is used in utensil handles, automatic skillet thermostat housings, and similar applications. It has withstood up to 450° F. for 24 hours.

Paper can be made fireproof by impregnating it with a new resin (*Synco 85*, Synco Resins, Inc.). The paper also shows the increased strength and chemical resistance characteristics of phenolic-impregnated materials. Paper so impregnated is expected to find application in air filters, insulation, honeycomb cores, overlays, and laminates.

An epoxy-based enamel (*Rexclad "R'*, Rexton Finishes, Inc.), available in almost any color including metallic, can be applied to phenolics at a cost of approximately 1¢/sq. foot. It is used on radio cabinets, steam iron handles, base plates for coffee makers, control switches on electric blankets, etc.

A new phenolic coating (*Phenoline 305*, Carboline Co.) produces a 12-mil protective phenolic surface with only two coats. It is a modified phenolic with 86% solids content, applies at 6 mils per coat, and is catalytically set. The coating is recommended for use on equipment, exteriors, ceilings, and concrete floors in corrosive environment.

condensing of methylol groups is the *A-stage* or *resol stage*. The resol is readily soluble in alkalies, and in solvents such as acetone. Resols are low-melting and of low molecular weight. The product at this stage is mostly phenol alcohol. As polymerization continues, the resins enter the *B-stage*. The B-stage resins, sometimes called *resitols*, are still fusible but are soluble only with difficulty. The *C-stage* or *resite* is considered to be the final cure of the resin and is represented by the curing in a mold of a molded part.

If a mol ratio of less than 1:1 of formaldehyde to phenol is used in combination with an acidic catalyst and reacted under proper conditions, the resultant resin is a *novolak* and is considered noncuring. Generally speaking, chemists recognize only one type of reaction between phenol and formaldehyde under acid catalysis. This reaction consists of a condensation of 1 molecule of formaldehyde with 2 phenol nuclei to form a methylene bridge with the elimination of water. This reaction takes place in either the ortho or para positions. As mentioned before, the end product of this reaction is a novolak which is permanently fusible and for practical purposes noncuring. In order to make this resin infusible and capable of being cured, a source of additional methylene bridges must be reacted with it. This is done through the addition of hexamethylenetetramine, commonly known as hexa. It is accepted by most authorities that the ammonia present in the hexa acts as the catalyst in furthering the cure of the so-called *two-stage* resins.

Available forms

Phenolic resins may exist in either solid or liquid form; sometimes alcohol solutions are used as varnishes.

Resins for phenolic molding compounds are generally available as powdery, finely-ground solids and are usually mixed with fillers, lubricants, dyes, pigments, etc., and further processed.

Liquid phenolic resins or varnishes are used extensively by the laminating industry in the manufacture of industrial and decorative laminates. Liquid resins are also used in the formulation of protective coatings and adhesives, and in numerous applications as an impregnant or as a bonding agent for wood, paper, etc. Casting resins are another prime outlet for liquid phenolic.

The foundry industry, in manufacturing shell molds, usually employs a solid resin, although recent activity has indicated some preference for a liquid resin.

Foamed materials are one of the newer forms of phenolic that has attracted considerable attention for insulation applications and sandwich constructions. Microscopic phenolic spheres are also used as a surface layer on the top of tank-stored petroleum products to prevent evaporation of the liquid, and as an ingredient of a new type of syntactic foam.

Molding compounds

Phenolic molding materials, sometimes called compounds, are produced in granular, nodular, or macerated forms. Fillers used in molding compounds consist of wood flour, cotton flock, macerated rag, varying lengths and types of asbestos fiber, mica, sisal, glass, and many other organic and inorganic materials. The most common form of molding compound, the granular type, is made by premixing the proper quantities of resin, filler, lubricants, and colorants, and processing this premix on heated differential rolls. This partially advances the resin and densifies the product. The material is stripped from the rolls in the form of a dense, brittle sheet which is then ground to the proper particle size.

A knowledge of the general effect of specific filler types is essential for the engineer so that he may properly design for existing end-use application. The molding compound supplier has done this for him by setting up such broad general compound classifications as general-purpose, impact-resistant, heat-resistant, shock-resistant, etc. Fully cured molded phenolic articles are durable, inert, dimensionally stable, and resistant to burning. They are inert to most common solvents

and weak acids. They are attacked rather rapidly by strong caustic solution. Generally speaking, phenolics are available only in dark colors since they tend to darken on aging or exposure to sunlight. Epoxy spray or dip coats can be used to color molded phenolic parts.

Phenolic molding compounds generally are molded at 3500 p.s.i. and curing temperatures are usually between 300 and 370° F. Phenolics can be molded by either compression or transfer methods and in almost any shape or size.

Laminating resins

One of the most important uses of phenolic resin varnishes is in the manufacture of industrial laminates as well as in decorative laminates such as those used for tabletops and countertops. The laminates are second only to the molding materials in consumption of phenolic resins and account for over 15% of all phenolic resins.

Special formulations of resins and varnishes can be used to manufacture many varieties of laminated products with varying characteristics. The laminating process consists essentially of running a paper or fabric through a solution of the phenolic resin or varnish and removing volatile materials in predetermined quantities. This is done by passing the treated paper or fabric through a circulating hot air oven at a predetermined rate. The dried and partially cured paper or fabric is then cut to proper size, a number of plies are placed one on top of the other, and the combination is loaded into a hydraulic press where pressure is applied. Polished plates in the press give a smooth surface to the finished laminate. Heat applied to the laminate while it is in the press gives it the final cure.

Coatings and adhesives

Approximately 6% of total phenolic resin usage is in protective coatings. Even though the poundage still sounds attractive, the growth picture in recent months has been relatively poor due to the advent of some of the newer synthetics such as the modified alkyds.

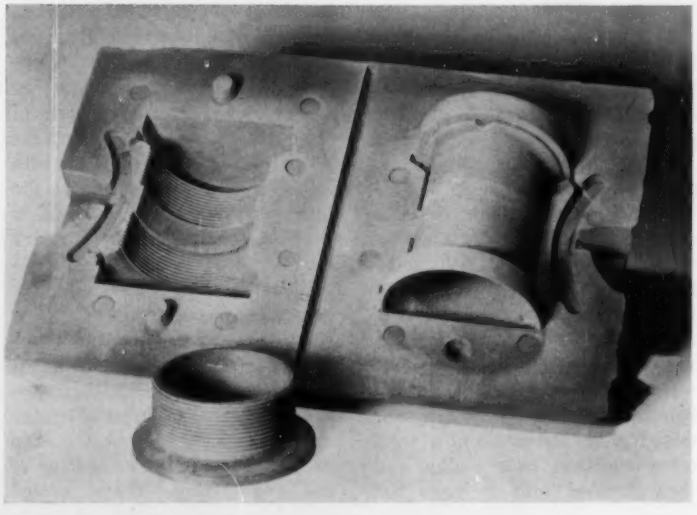
Phenolics as protective coatings, however, have been in use for a good many years and therefore are worthy of mention. The two types used are straight phenol-formaldehyde resins and resins that have been modified with an ester gum to impart hardness and gloss to the finished product.

Phenolic resins used for adhesives generally are characterized as hot-setting adhesives. They require heat and usually pressure to effect a satisfactory cured bond. Generally speaking, the resins used in the manufacture of adhesives are of the same general type as those used in the laminating industry. With the correct selection of phenolic resins, bonds can be effected that are as strong as the base material itself and in some cases considerably stronger.

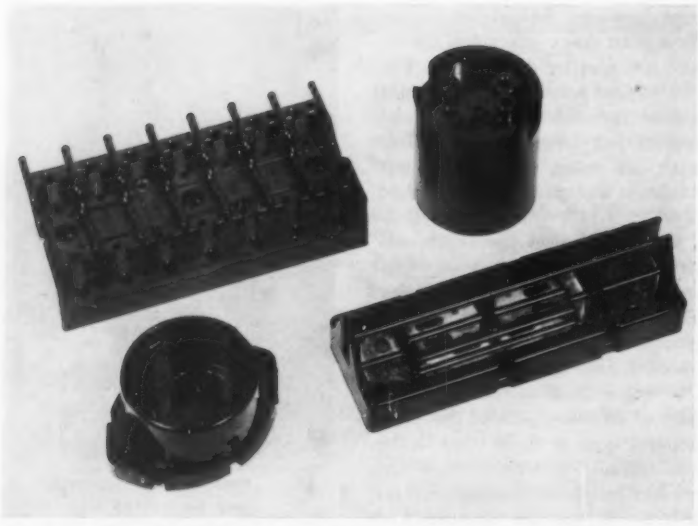
For reasons of economy phenolic liquid resin adhesives can be partially extended with inert fillers, such as walnut shell flour, without greatly affecting the bond strength. Temperature ranges usually employed run between 250 and 350° F. and pressures up to 300 p.s.i. are used for bonding.

The plywood industry uses almost 10% of all the phenolic resins manufactured. This is the largest single application for adhesives.

Phenolic resins are also used extensively in the bonding of waste wood and particle wood in the manufacture of structural board for many purposes.



Phenolic-rubber compound is used for molding brake motor collector ring. Brass rings are molded in. (Photo, G.E.)



Casting phenolics

Cast phenolics are widely recognized in certain decorative applications such as special cast shapes for cabinets, buttons, and poker chips.

Though not as well-known to the general public, industrial castings are of far greater importance. Cast phenolics are the cheapest of the casting resins in

Sand shell foundry molds bonded with phenolic resin allow metal casting to close tolerances, save thousands of dollars annually in machining costs. (Photo, G.E.)

Intricate accessory switch components are automatically molded of new one-stage phenolic molding compound especially formulated for fast cure. (Photo, G.E.)

wide use today. Liquid phenolic resin types are used in casting with a solid content of 50 to 90%, depending on formulation and the degree of advancement. Molds for casting phenolic resins can be made quickly and cheaply from a wide variety of materials. They are most commonly made from plaster of paris and lead. Cast phenolics must be cured slowly to avoid bubbles, crazing, and excessive shrinking. Hardness, rigidity, excellent dimensional stability, good strength, and resistance to both abrasion and impact are the characteristics that have led to their wide acceptance.

Bonding agents

The use of phenolic resins in thermal insulation and in the manufacture of brake bands accounts for almost 15% of total phenolic resin usage.

In the application of phenolic resin as a binder in glass wool insulation, the phenolic resin is sprayed onto the glass fibers as they drop down through the spinning tower. The coated fibers are then deposited on a moving belt, compressed to the desired thickness, and oven-cured.

In the manufacture of brake bands, powdered phenolic resin is mixed with asbestos fiber and other additives in a muller and then pressed into a large flat sheet. Before curing is completed, these sheets are rapidly cooled and the brake band segments are die-cut to the proper shape. These segments are then formed over a suitable forming fixture with heat and pressure and the final cure is achieved.

Foundry industry

Although the foundry industry accounts for only slightly more than 2% of the total phenolic resin usage, this application has the brightest growth picture of all. Within the last few years phenolic resins have been used in an increasingly larger quantity in the foundry industry because of the economic advantage gained through their adaptability to smoother castings, closer tolerances, and less machining.

The basic process consists of mixing relatively low percentages (4 to 8%) of phenolic resin with foundry sand. Depending on the process used, this might be either a dry mix or a wet mix. The dry mix has the disadvantage of segregation of resin and sand but possesses the advantage of low capital investment for the foundrymen. The wet process or the coated sands requires higher capital investment in terms of equipment necessary to coat the sand properly. It has the advantage of not segregating. These coated sands are blown onto a hot pattern; the layer of material which adheres to the pattern is cured by the heat. The process of using the coated sands enables the foundry to reduce resin content considerably. Even though the individual application uses little resin, the economic picture is attractive. It is expected that many more foundries will utilize the process and thereby increase considerably the total poundage of phenolic resins for foundry industry use.

PHENOL-FURFURAL

Even though formaldehyde is the most commonly accepted aldehyde used in reaction with phenol, furfural is used to some extent because of the modifying characteristics that it can give to a phenolic resin. Phenol-furfural resins have been made for a good many years, the basic patents having been issued between 1921 and 1929. Development of techniques for large-scale production of furfural from waste oat hulls helped stimulate activity in this field.

The chemical nature of furfural is responsible for its ability to condense with itself to form a polymer. Not only does the aldehyde group enter into this reaction but so also does the furan ring, providing a cross-linked molecular chain. Furfural resins possess excellent chemical resistance and are capable of high strength.

Phenol-furfural resins are used primarily as modifiers with standard phenolic resins to impart special characteristics to the molding compound. Furfural resins are characterized by extreme duration of flow at lower temperatures and very rapid cure rates at higher temperatures. By judiciously balancing the amount of furfural resin included in a standard phenolic formulation, molding compositions can be manufactured with exceedingly long duration of flow characteristics. This is exemplified by the earlier work on large television cabinet moldings. The early success of these phenolic television cabinets was due in large measure

to the incorporation of furfural resins to give the long duration of flow necessary.

By curing at elevated temperatures (375 to 400° F.) cures can be obtained that are faster than those obtained with the straight phenol - formaldehyde resins.

As modifiers, approximately 1 million lb. of phenol-furfural resins are manufactured per year.

RESORCINOL-FORMALDEHYDE

Resorcinol aldehyde reactions are very similar to phenol aldehyde reactions except that the resorcinol is much more reactive than phenol. This is, of course, due to the fact that there are two activating OH groups as opposed to the one activating group in phenol. Resorcinol has the highest rate of reaction with an aldehyde of any common phenolic body. This high rate of reactivity has made resorcinol resins extremely difficult to control and has somewhat limited their usage. Control can be attained, however, by reacting with a deficiency of aldehyde. This results in a very stable resin which can be stored for long periods of time, as long as the material remains deficient in aldehyde content.

Cures are attained by adding a source of more aldehyde, usually paraform, to obtain room temperature cures. These cures are essentially neutral and therefore the resorcinol aldehyde resin does not degrade fibers or other structures. This characteristic is extremely important in gluing or bonding. Because of the exceedingly high rate of reactivity, resorcinol resins are capable of exceedingly fast cures. The idea of a molding compound with exceedingly fast cures has intrigued the material supplier for many years. Available literature advises that the addition of small quantities of resorcinol resin can speed the cure of phenolic molding materials. However, due to the extreme critical nature of controlling this reaction, no composition has been manufactured which would either consistently produce low cures or could be manufactured with reasonable facility.

The outstanding usage of resorcinol resins is as adhesives. These glues have outstanding characteristics. The bond is fungusproof and is not affected by moisture or boiling water. These characteristics make it ideally suited for bonding plywood, and the plywood industry uses most of the resorcinol resins made. The process, known as assembly gluing, takes advantage of resorcinol adhesives in the manufacture of arches and structural members made from wood. It is also used to a large extent in boat construction.

Since resorcinol resins are expensive, it is common practice to blend phenolics with them in proportions that will still allow room temperature cures to be attained. Further economies can be achieved by extending still further with phenolic resins and gluing by means of a hot-pressing technique. These resin adhesives are extensively used in wood cabinet making. These adhesives are characterized by their high affinity for wood and they are the only low-temperature setting adhesives which also have maximum resistance to exposure.

Polyester (Alkyd) Resins

BY W. O. ERICKSON* and V. W. GINSLER*

The esterification reaction between polyhydric alcohols and polybasic acids produces a large class of materials known as polyester or alkyd resins. These resins exhibit a wide range of properties and are utilized in highly diversified commercial applications. The wide range of properties results largely from the type and proportions of chemical components used in manufacture.

When a saturated dihydric alcohol (i.e., one containing no double bonds) is reacted with a saturated dibasic acid under controlled conditions, water is evolved and chain molecules having terminal hydroxyl or carboxyl groups result. These molecules are the saturated polyesters. They can undergo further intermolecular condensations but cannot be cross-linked.

When a dihydric alcohol and a dibasic acid, either or both of which contain a doubly-bonded pair of carbon atoms, are reacted, an unsaturated polyester is obtained. The double bonds render the unsaturated polyester capable of subsequent cross-linking. The unsaturated polyesters usually are blended with a reactive monomer (such as styrene) and reacted under the influence of special catalyst systems. The polyester and the monomer copolymerize to form a thermoset.

There is considerable confusion in references to the type of polyesters involved in various applications. By chemical definition, the reaction product derived from a polyhydric alcohol and a polybasic acid, whether or not the reaction product is modified by special alcohol or acid components, is still properly called a polyester. For practical purposes, however, an oil-modified polyester (i.e., a fatty acid-modified polyester) always is referred to as an alkyd or alkyd coating resin. To add to the complication, because the alkyd rather than the polyester designation was chosen to refer to certain proprietary molding compounds introduced some years ago, the practical usage of alkyd molding compounds now has been established. Certain saturated polyesters have become useful plasticizers and often are referred to as polymeric plasticizers. Other special polyesters are formed into film and textile products. A polyester product is a principal ingredient of polyurethane foams.

POLYMERIZABLE (UNSATURATED) POLYESTERS

The polymerizable polyesters are a relatively new class of resins that first appeared commercially during World War II. They are noted especially for ease of handling, good physical and electrical properties, and speed of cure. Initial applications were in combination with fibrous glass in radomes, body armor, and various nonstructural aircraft parts.

After World War II, gradually lower resin costs, better technical know-how, and improved production techniques helped result in an increasing number of applications.

Polyester resin volume in 1956 was approximately 64 million lb., about a 33% increase over the 48 million lb. sold in 1955. This class of resins now is used for matched-metal molding, premix materials, laminates and hand lay-up applications, casting, and encapsulation.

Chemistry

A polyester, as the term is used here, refers to an unsaturated polyester base resin dissolved in a polymerizable monomer. The base resin component can be prepared from innumerable chemical combinations. It is this base component that usually is modified to obtain the various properties of the finished polyester.

Essentially, dibasic acids and dihydric alcohols are heated to sufficiently high temperatures to react, split out water, and form ester linkages. As the reaction proceeds, many ester linkages are formed in one linear molecule. It is essential that at least a certain portion of the dibasic acids or the dihydric alcohols be unsaturated, i.e., contain double bonds, to provide for the function of copolymerization. It is through the connecting of these double bonds with those of the monomer that curing takes place.

The dihydric alcohols most commonly used are glycols of ethylene, propylene, 1,3- and 2,3-butylene, diethylene, and dipropylene. Unsaturated dihydric alcohols are not commercially available. The dibasic acids, therefore, must supply the necessary unsaturation or double bonds to the polyester base resin. The unsaturated dibasic acid is usually maleic anhydride or fumaric acid. The most common saturated dibasic-acid components are phthalic anhydric, and adipic and azelaic acids.

The polymerizable monomer can be styrene, vinyl-toluene, diallyl phthalate, methyl methacrylate, or triallyl cyanurate.

Under the influence of heat and/or peroxide catalyst, the monomer and unsaturated polyester base copolymerize. No gas or liquid is evolved during the cure. The curing reaction is exothermic and the heat evolved aids in speeding the cure. The particular nature of this polymerization provides the vital factors of speed and simplicity so important in field applications of polyesters.

Fabricating methods

The main fields of application for the polymerizable polyesters are hand lay-up, preform, mat and premix molding, and casting.

The hand lay-up method is used to make large shaped articles such as boats and radomes. Fibrous glass mat or cloth sup-

Recent Developments and References were prepared by the editors.

A polycarbonate resin (*Lexan*, General Electric Co.) offers an unusual combination of toughness, heat resistance, impact strength, and dimensional stability. The manufacturer expects this thermoplastic material to replace cast metals, ceramics, and other plastics in some applications. It is suggested for applications such as coil forms, appliance parts, gears, housings, structural parts, electronic components, and telephone accessories.

Prescription lenses of an allyl base copolymer (*Enduron Prescription Lenses*, Pioneer Scientific Corp.) are manufactured in a full foci range, including bifocals and cataract lenses, and comply fully with the latest standard opthalmic and Federal specifications. Although this material does not have the abrasion resistance of glass, it is 30 to 60 times more abrasion-resistant than most other optical plastics.

Polyester resin especially formulated for rapid casting or embedding is available in low-cost educational-experimental kits for the student, inventor, model maker, or product design engineer (*Chemiglas*, Technicraft Co.).

A fire-resistant light-stabilized resin (*Hetron 93LS*, Durez Plastics Div., Hooker Electrochemical Co.) is used to make glass fiber-reinforced corrugated sheet which has been fire-tested and approved for unlimited use as industrial glazing. Two additional polyester resins were announced by this company. One (*Hetron 72*) combines good chemical resistance, fire resistance, and excellent heat resistance; the other (*Hetron 32A-LS*) is a semirigid resin with outstanding physical properties, fire resistance, and weather stability which meets the requirements of MIL R 7575A and is of special interest for large radome structures. A transparent lacquer (*Hetrolac 105*), when applied in very thin coatings, extends the life of glass-polyester compositions exposed to weathering.

A silica-filled polyester resin composition (*Haveg 7010*, Haveg Industries, Inc.) was developed for use with brick and tile tank linings and for laying floors and walls in chemical processing areas. This polyester cement is said to resist a wide range of chemicals, including both acids and mild alkalies at high temperatures, concentrated alkalies at room temperature, and oxidizing agents. Service temperatures up to 265° F. are recommended.

A complete line of polyester resins (*Amester*, American Alkyd Industries) includes a general-purpose resin (*Amester 722*), a light-stabilized resin (*722 L.S.*), a reactive resin (*502*), matched-metal die resins (*552*), a low viscosity resin (*722 L.V.*), a thixotropic resin (*822*), a fire-retardant resin (*852*), a flexible resin (*922*), and a gel coat (*1022*).

A general-purpose molding resin (*MR-42R*, Celanese Corp. of America) has good resistance to crazing or cracking in resin-rich areas of the molding. Molding cycle, mold release, lack of mold scumming, degree of fiber wetting, hot strength of molded part, surface gloss, and resistance to warping are equal or superior to similar resins. This resin is also promising in the premix molding field.

A new thixotropic agent (*Thixcin E*, Baker Castor Oil Co.) effectively inhibits crawling, sagging, draining, and pigment setting in polyester resins. The additive is characterized by easy stir-in, with maximum results attained at temperatures of 90 to 110° F. As little as 0.2% imparts a highly thixotropic body.

Transparent conductive coatings (*Sierracote*, The Sierracin Corp.) which are essentially metallic in nature may be deposited by special high-vacuum techniques on glass or other chemically stable glazing materials such as a cross-linked polyester plastic (MIL-P-8257A).

A modified polyester-type adhesive (*46971* Adhesive, E. I. du Pont de Nemours & Co., Inc.) for polyester film (*Mylar*) was developed to overcome rapid evaporation of methylene chloride and consequent difficulty in roller coating or gravure printing. The solvent used in the new product is 1,1,2-trichloroethane. This company supplies three classes of adhesives for Mylar: 1) modified synthetic rubber type, 2) vinyl type, and 3) polyester type.

---

plies the necessary reinforcement. Either a male or female mold can be used. The polyester-fibrous glass laminates are laid up against the mold. Sometimes a bag of impervious material is placed over the laminate, and either vacuum or pressure used to hold it in place during cure. Curing can be at room or elevated temperature. Production is slow.

Preform or mat molding utilizes heated, matched-metal molds. The mat or preform is placed into the heated mold, the catalyzed polyester is poured in, and closing the mold forces the resin throughout the reinforcement. Conventional molding cycles are 2 to 4 min. at 220 to 260° F. and 50 to 200 p.s.i.

Premix molding provides a rapid method of making less critical parts at considerably lower cost than mat or preform molding. It makes possible the molding of parts with varying wall thicknesses, intricate contours, and molded-in inserts. In this method, resin, reinforcement, filler, and catalyst are mixed in a dough-type mixer. The resulting material varies from a putty- to straw-like mass depending on composition. Typical molding cycles are ¾ to 2 min. at tempera-

tures of from 270 to 300° F. and at pressures of from 500 to 1500 p.s.i.

In the casting field, little if any reinforcing agent is used. Castings are made from both clear and filled resin by pouring the catalyzed resin into a mold. Curing can take place at room or elevated temperature.

Properties and uses

The important general properties typical of all polymerizable polyesters are: 1) Ease of handling. Polyesters in the uncured state are easily handled liquids. They cure to a solid material with no liquid or gases evolved. 2) Rapid cure for thermosetting resins. 3) Ease of coloring. Polyesters are light-colored liquids which can readily be pigmented to any desired color. 4) Excellent dimensional stability. 5) Good electrical properties. 6) Good physical properties.

Specialty type polyesters designed for specific applications can have one or a combination of additional properties:

1) Good weathering resistance and light stability; 2) heat resistance—the use of monomers, such as triallyl cyanurate, in conjunction with highly unsaturated polyester bases, raises the operating temperature of polyester-fibrous glass laminates to 500° F.; 3) flame resistance; and 4) corrosion resistance.

Polyester resins are so widely used that only a listing of the major fields can be given here.

Building panels are a major

utlet for polyesters and are designed to take advantage of the material's ease of handling, good weathering resistance, ease of coloring, and good physical properties. These sheets are made in light transmissions varying from 5 to 80 percent. They are used principally as skylights, industrial glazing, and awnings.

Premix materials constitute one of the fastest growing segments of the polyester field at present. Major end uses are electrical equipment parts, refrigerator striker plates, automotive heater ducts, automotive air conditioner parts, and automotive garnish moldings (window frames).

Matched-metal moldings are represented by cafeteria trays, tote boxes, chairs, laundry tubs, washing machine tubs, automotive parts, luggage, and boats.

Hand lay-up applications, which were the first large-scale applications of polyester resins, are still major production items. Radomes up to 36 ft. in length are being produced, boats up to 24 ft. long are in volume production, and tanks of various types are being made for the storage of certain corrosive liquids, for electroplating baths, and for similar uses.

Castings are being produced for aircraft glazing. Filled castings are being used in electrical components. Decorative castings are the most rapidly growing segment of this field. Polyester buttons are produced in quantity.

[1] Adapted from "Theories and facts concerning alkyds," by K. A. Earhart, Ind. Eng. Chem. *41*, 716-725 (1949).

Commercial polyesters

Polyesters available commercially may be designated as general-purpose, resilient, flexible, flame-resistant, light-stabilized, heat-resistant, and corrosion-resistant. In general, the resins commercially available range in stiffness from rigid to flexible when cured. Typical properties are given in Tables I, II, and III (p. 142).

ALKYD COATING RESINS

Polyester resins used in organic coatings are usually known as alkyds. Alkyds are distinguishable from other polyesters in that they contain fatty monobasic acids as "oil modifications" and are usually furnished in solvents. Because of popular usage, these polyester resins will be referred to as alkyds throughout the discussion of coating resins.

The predominant group of alkyd resins used in the manufacture of surface coatings employs phthalic anhydride as the main polybasic-acid constituent and such polyhydric alcohols as glycerol or pentaerythritol. Other polyhydric alcohols, such as glycols, di- or tri-pentaerythritol, sorbitol, or trimethylolethane, can be used to emphasize special resin properties. In addition to the polybasic acid and polyhydric alcohol components, alkyd resins for protective coatings are modified with oxidizing or non-oxidizing fatty acids derived from vegetable and, in some cases, marine oils.

Oil-modified alkyd resins of the air-drying type cure by oxidation of their drying oil constituent. In the case of the baking type, in which the oil modification may be oxidizing or non-oxidizing, the alkyds cure by co-condensation with alkylated amino resins in the presence of heat.

Quantitatively and qualitatively, the oil modification of alkyd resins produces profound effects on the properties of these products. Alkyds generally contain from 30 to 70% of oil and, depending on their specific range of oil content, are classified approximately as follows:

Classification	Oil content, %
Short-oil	30-46
Medium-oil	46-56
Long-oil	56-70

The general quantitative effect of oil content on alkyd resin properties is expressed graphically in Table IV, above, wherein the values of the various properties listed increase in the direction shown by the arrows. Broken arrows are used when the solvent has a bearing on the property.

Table V, p. 144, illustrates the qualitative effect of the type of oil used on the properties of the alkyd.

Short-oil alkyds

Short-oil alkyds contain fewer of the aliphatic, solvent-tolerant, fatty-acid chains in their molecular structure, and, hence, are prone to be incompatible in aliphatic solvents. These alkyds are supplied as solutions in aromatics, such as xylene or toluene. The short-oil alkyds that are modified with non-oxidizing oils, such as coconut or castor oil, are used as plasticizers in cellulose nitrate lacquer formulations to contribute the necessary properties of adhesion, flexibility, durability, and color retention to

TABLE V: Effect of type of oil on properties of alkyd resins[1]

modern automotive and other fast-drying industrial lacquer finishes. Short-oil, non-oxidizing alkyds are also used extensively with urea and melamine resins in baking enamels and yield exceptionally hard, tough finishes for refrigerators, washing machines, home freezers, and many other similar types of home appliances.

Short-oil, oxidizing alkyds based on soya, dehydrated castor, or cottonseed oils have a broad base of utility in industrial baking finishes of all types. In conjunction with acid-catalyzed urea resins, they have also found successful application in forced-dry, wood-furniture finishes that are superior in abrasion resistance, impact strength, and durability to oleoresinous varnishes or cellulose nitrate lacquers.

Medium- and long-oil types

Medium- and long-oil alkyds that are soluble in mineral spirits are modified most frequently with oxidizing oils and are used in brushing-type, air-drying finishes. Many government specifications call for alkyds of this group and most of the familiar household paint products, such as alkyd, flat wall-paint, 4-hour high-gloss enamel, and porch, floor, and deck paints, are manufactured, at the present time, from either the medium- or long-oil type alkyd resins.

Availability of "odorless" and "low-odor" mineral spirits has permitted development of medium- and long-oil alkyd resin solutions in these solvents for interior alkyd-based flat paints and gloss enamels that are free from obnoxious odors. These products have shown a gain in usage in a market that only several years ago seemed to be headed toward complete domination by water-thinned latex paints. Long-oil and extra-long-oil alkyds at 100% solids are also increasing in usage as modifiers for various water-dispersed latices and as components of exterior house paints.

Modified alkyds

Oil-modified alkyd resins may be modified further by processing with other materials for the emphasis of special properties. Common modifiers (see Table VI, below) are rosin, phenolic resins, styrene, and silicones. Such additional modification, however, is usually a compromise in which some properties are gained and others lost.

Highly thixotropic alkyds have been developed by modification with polyamide resin. Paint products produced from polyamide-modified alkyds are unusual in appearance in that they are jelly-like, but are quickly reduced to ordinary consistency by mechanical agitation.

Non-phthalic alkyds

Rosin or terpenes, and maleic anhydride or fumaric acid undergo a Diels-Alder reaction and form a tribasic acid. This reaction product can be esterified with glycerol or fatty-acid glycerides to produce alkyd resins that exhibit properties superior to those of the varnishes manufactured by simply cooking maleic-modified ester gum with oils. Although these alkyds cannot be considered equivalent-quality substitutes for phthalic alkyds, they fit into a small sphere of utility for special applications.

Use of alkyd resins in the surface-coatings industry has risen considerably faster than the increase in paint production during the past 25 years. Alkyd resin production (solids basis) reached 241 million lb. in 1946; approximately 450 million lb. were produced in 1955 and probably close to 500 million lb. in 1956. This substantial growth is due to versatility, uniformity, and economy.

Versatility: Alkyds, in general are better coatings than oleoresinous varnishes and are adaptable to a wide variety of air-drying and baking finishes for wood, metal, plaster, paper, and plastics. In addition, alkyds function as plasticizers for cellulose nitrate.

Uniformity: The growth of al-

TABLE VI: Modifiers for alkyd resins

Modifying agent	*Advantages contributed*	*Disadvantages contributed*
Rosin	Fast drying Hardness Mar resistance	Yellowing Poor exterior durability
Phenolic	Hardness Solvent resistance Alkali resistance	Yellowing Poor stability
Styrene	Fast drying Light color Color retention	Poor solvent resistance Poor stability
Silicone	Heat resistance Hardness Resistance to thermal shock	Cost Higher curing temperature

kyd resin production has fostered development of a new scientific attitude in the paint and varnish industry. Careful chemical controls required for successful alkyd production have replaced the individual judgment of the varnish maker and a new order of uniformity has resulted.

Economy: Alkyd resins are low in cost. Their raw materials are available to the manufacturers in abundant supply. The efficiency of handling packaged, ready-to-use vehicles of high quality and wide scope represents a greater stride in progress than any that the paint-making industry has made throughout its entire history.

ALKYD MOLDING COMPOUNDS

When suitable polyester resins, capable of cross-linking, are properly compounded with fillers, pigments, and catalysts, thermosetting molding compounds result that have rather unique properties. Known as alkyd molding compounds, these materials are fast-curing and may be made to flow around delicate inserts in intricate shapes. Fast-closing presses are required and, depending upon the thickness of the part, cure times of 10 to 50 sec. are possible. Molding temperatures are usually in the range of 300 to 315° F., with molding pressure varying in the range from 800 to 1500 p.s.i.

Moldings exhibit excellent dimensional stability and electrical characteristics. Their arc resistance and elevated temperature service up to 400° F. are of particular interest. Moisture- and solvent-resistance is good.

The molding compounds may be filled with a mineral filler or reinforced with fibrous glass. The mineral-filled products are in both putty and granular forms. The putty form is particularly useful in encapsulating small electrical resistors and capacitors. The granular types are free-flowing and adaptable to automatic molding operations. Numerous electronic components, such as tuner boards, tube bases, and connectors, are in production. The granular types are also finding their way into automotive ignition applications.

The fibrous glass-reinforced materials are usually in mat form and are characterized by their high strength. These materials have found widespread use in applications where a combination of high strength and good electrical properties is important. Thus, these materials are used in such applications as insulating brackets and bases, rocker rings, circuit breaker cases, and coil forms.

The alkyd molding compounds are more reactive by nature than other thermosets and, therefore, are more sensitive to handling and storage conditions.

OTHER POLYESTER PRODUCTS

Included among other polyester products are the following:

Plasticizers: A number of polyester plasticizers are available commercially. In general, they are saturated resins of controlled molecular weight. The polyester plasticizers are more viscous and, because of their low volatility, are more permanent than other esters used for plasticizers. They may be used in both organic coatings and plastics.

Fiber and film: A special type of saturated polyester prepared from ethylene glycol and terephthalic acid has found application in the textile fiber field and as film. Clothing fabric woven with fibers (Dacron) of this polyester has good wear resistance and laundering characteristics. The film (Mylar) features well-known tensile strength and tear resistance and is finding ready application in electrical and packaging applications.

Polyurethane resins: Other saturated polyesters with lower molecular weights and differing compositions are entering the rapidly expanding field of polyurethane resins. The polyesters are used in conjunction with diisocyanate compounds to form foams and elastomers as well as coatings.

Saturated polyesters and diisocyanates of appropriate composition can also be reacted to form polyurethane elastomers capable of being cross-linked, by reaction with suitable agents, to form extremely tough and wear-resistant rubber products.

Protein Plastics: Zein, Casein

Proteins belong to the category of high polymeric materials. Inasmuch as there are some 20 alpha-amino acids known to be constituents of proteins, there are that many possible monomers, the alpha-amino and adjacent carboxyl groups, which form the backbone of the polymers, while the other groups form the side chains. These side-chain groups include amino, amide, carboxy, aliphatic hydroxy, phenolic, guanidyle, indole, imidazole, thiol, and disulfide. They are apparently spaced regularly along the chains and vary greatly in amounts in the different proteins. These are the reactive parts of protein molecules and are responsible for fundamental differences between proteins and for the extreme complexity of these natural polyamides.

The fibrous proteins (keratins, such as horn, tortoise shell, hoofs, claws, hair, and feathers) resist solution and deformation by heat. The globular proteins (casein, soybean, and zein) readily dissolve and are thermoplastic.

Potentially low-cost proteins include soybean, zein, peanut protein, and keratins. Molding powders can be made from the reaction product of keratin-containing horn powder, urea, and formaldehyde. Peanut protein has suitable characteristics for use as glue. Soybean and peanut proteins are used as extenders of phenolic resin in plywood.

ZEIN

BY D. M. RATHMANN*

Zein belongs to the class of aqueous alcohol-soluble proteins known as prolamines. Although first isolated from corn in 1821, zein did not become commercially available until 1939. Applications since that date have taken advantage of its solubility in organic solvents and its film- and fiber-forming characteristics.

Like all proteins, zein is a naturally-occurring high polymer composed of amino acid groups united by peptide linkages. The high proportion of acidic, amide, and nonpolar side chains accounts for its solubility in many organic solvents.

Zein is a product of the corn wet-milling industry. Gluten, which contains most of the protein in the corn kernel, is separated from the starch and other constituents. Zein is then extracted from the gluten with organic solvents.

Processing and fabricating

Solutions of zein in organic solvents or aqueous systems are adaptable to a wide range of coating, film, and fiber applications. As a general rule, a solvent for zein must contain at least one functional group of the type hydroxyl, carboxyl, amide, or amine. Zein is unique among the industrially available proteins in being soluble in methanol, in aqueous ethyl and isopropyl alcohols, and in the lower-molecular-weight glycols and glycol-ethers.

Secondary solvents, which will not dissolve zein but which enhance its solubility in a primary solvent, include lower ketones, aliphatic esters, chlorinated hydrocarbons, and the higher glycol-ethers. These materials are particularly useful because they permit modification of such properties of zein solutions as evaporation rate or viscosity; they also promote the compatibility of various resins and plasticizers. Alcoholic solutions of zein tolerate limited amounts of diluents such as toluene, xylene, benzene, and naphthas.

Zein is insoluble in water but is readily soluble in aqueous alkalies at a pH of 9.5 to 11. Zein, unlike many other proteins, is not dispersed by weak alkalies such as ammonia or borax. Dilute aqueous solutions of strong alkalies dissolve zein but concentrated solutions do not. Useful aqueous systems are formed with ammonium or sodium resinates. Various synthetic detergents, such as the sodium alkyl aryl sulfonates, produce neutral aqueous solutions of zein having good film-forming properties. Methods have been developed for the preparation of emulsions that are neutral, stable water systems having high solids content and water-thin viscosity. Films prepared from these emulsions are comparable to those made from organic solutions.

Plasticizers for zein compositions include higher glycols, sulfonamides, fatty acids, amides, esters, and amines.

Fusion resins are made by blending zein with natural or synthetic resins and plasticizers. As in the case of solvents and plasticizers, resins containing highly polar groups and a proper balance between polar groups and hydrocarbon residues are fully compatible with zein. Many materials that may be classified as incompatible have been incorporated into zein systems by the use of mutual solvents, plasticizers, and resins.

Increased tensile strength, greater toughness, and higher water resistance are imparted to zein compositions by curing with formaldehyde. Because few primary amino groups occur in the zein molecule, reaction with formaldehyde proceeds at a slower rate than in the case of proteins containing these groups. Curing is accelerated by catalysts such as strong mineral acids or their ammonium salts, and by heat above 70°C.

Properties

Zein is the only industrially available protein soluble in organic solvents. This property gives the material many fields of application not open to other proteins. Zein is compatible with a wide range of natural and synthetic resins and plasticizers. In addition, it is soluble in dilute

* Corn Products Refining Co., 17 Battery Pl., New York, N. Y.

References were prepared by the editors.

aqueous solutions of strong alkalies, and is dispersed by various resinates and synthetic detergents.

Unlike most other proteins, zein is highly resistant to microbial attack. Films and coatings are tough, glossy, scuff-resistant, and greaseproof. Fibers have wool-like properties, high tensile strength, and notable resistance to acids, alkalies, and organic solvents.

General properties of zein

Molecular weight	about 25,000
Specific gravity (at 25° C.)	1.25
Isoelectric point	6.2
Dielectric constant	4.9–5.0
Decomposition point (° C.)	180–200

Applications

Vicara brand textile fiber is produced from aqueous alkaline solutions of zein by extrusion into acidic-salt hardening bath and curing with formaldehyde. Properties are described in the Fibers Chart.

Composition cork is produced by mixing cork granules with a solution of zein and formaldehyde in a glycol-type solvent. By application of pressure and heat, the zein is cured and set to a water-resistant binder. This composition cork is suitable for use in gasket sheets and bottle cap liners; it has excellent flexibility, compressibility, water resistance, and oil resistance.

Alcoholic solutions of zein and a compatible resin are particularly adapted to use as label and overprint varnishes which are tough, glossy, and scuff-resistant.

Highly grease-resistant and greaseproof coatings can be applied to paper and paperboard from solutions of zein. The zein emulsions are particularly suitable for the preparation of grease-resistant coatings on paperboard and avoid objections to the use of organic solvent systems.

Vehicles for various types of printing inks consist of zein (alone or modified with resins) dissolved in glycols or alcohol.

Fusion resins, made by blending zein with resins and plasticizers, may be ground to powders and either dissolved in solvents to give coating solutions or mixed with fillers to form molding powders.

CASEIN

Formaldehyde-hardened casein plastics were developed in Europe and their manufacture began there about 1900. Commercial development in this country did not get under way until after the original patents had expired. The basic patents covering the production of a tough, insoluble hornlike mass from casein by the action upon it of formaldehyde were taken out by two Germans, Krische and Spitteler, in 1900.[1]

Formaldehyde is the only agent which has as yet been economically successful in transforming casein into usable plastics. It is more accurate, therefore, to use the term casein-formaldehyde plastics than to call them casein plastics. Reaction with formaldehyde undoubtedly takes place through the polyamide groups and results in a cross-linked polymer.

Casein also reacts with aluminum salts in water solution to produce a stiffer, more stable material than casein itself. The casein-alum, unlike the casein-formaldehyde, is thermoplastic, hence may be extruded or molded with heat and pressure. Immersion in water breaks down the complex, leaches out the alum, and leaves the original casein.

Casein can be modified by acetic, propionic, and *n*-butyric anhydrides to produce derivatives that can be molded into articles having greater resistance to water. However, this reduction in water uptake is not entirely beneficial, since it is accompanied by a decrease in the strength characteristics of the molded casein articles.

[1] U.S. Patent 646,844; German Patent 127,942.

Manufacture

Conventional processing involves mixing ground rennet casein with water, dyes, and pigments; further processing in a screw extruder; extrusion as rods, tubes, or ribbons; hardening by immersion in a 5% formaldehyde solution for periods varying from a few days to several months (depending upon the dimensions of the piece); and drying. The cured plastic can be shaped somewhat with heat and pressure, and can be fabricated into a variety of end products.

Casein-formaldehyde plastics have generally good impact strength, some elasticity, and properties characteristic of thermosetting materials. A wide range of color effects is possible. Hygroscopicity and dimensional instability, however, have been limiting factors to their extensive application.

Forms available

Casein plastics are available in sheets approximately 16 by 20 in. by 2, 3, 4, and 6 mm. in thickness; other thicknesses up to 12 mm. are made to order. Standard size rods are approximately 41 in. long in diameters from ⅛ to ¾ in. inclusive. Rods smaller than ⅛-in. diameter are ground to size. Tubes are made to order in diameters up to 1 in. with bores of various diameters. Disks are available in any desired size from ⅜ to 2½ in. in diameter, varying from 2 to 8 mm. in thickness.

Special forms include button blanks, loops, rings, buckles, beads, game counters, and push-buttons, as well as handles and the like.

Silicones

BY PAUL A. GOODWIN*

RECENT DEVELOPMENTS

A heat-resistant laminate (Swedlow Plastics Co.), designed for aeronautical applications, affords an efficient barrier to heat transfer at temperatures up to 1200° F. The laminate is composed of fibrous glass fabric, high-temperature-resistant silicone resin binders, combinations of highly reflective metalized surfaces, and inert substances for added resistance to surface corrosion.

A glass-silicone grade of laminated plastics (*G-7-2*, The Formica Co.) has greater hot strength and better color fidelity, less water absorption, lower wet power factor, and higher dielectric strength than laminates heretofore available. The material is useful in electrical and electronic applications.

Transparent silicone-based rubber is being tested by the Air Force as an interlayer in windshield glass of new supersonic airplanes. The high heat of air friction softens the flexible, transparent vinyl butyral now used as a windshield interlayer, making it incapable of preventing the glass from shattering if cracked. The new interlayer retains adequate strength up to 350° F. as compared to the 180° F. limit on present interlayers.

A silicone rubber (*Silastic 916*, Dow Corning Corp.) combines high strength with thermal stability. Parts or components fabricated from this material retain high tensile strength, elongation, and tear resistance in high-temperature service. It has the good electrical properties normally associated with silicone rubber and is serviceable from —130 to 500° F. The material is suitable for molding, laminating, extruding, or calendering and it can be hot-air vulcanized.

The insulation resistance of miniature 26-contact connectors molded from silicone material (*Dow Corning 301 Molding Compound*, Dow Corning Corp.) was initially higher than comparable parts molded from mineral-filled melamine, glass-reinforced alkyd, and Orlon-filled diallyl phthalate. This advantage increased after exposure for 240 hr. at 96% relative humidity and room temperature.

The history of the silicones began in the 1870's with the work done by research chemists such as Landenburg in Germany and, later, Grignard in France. Earlier, silicon metal had been discovered in 1824 by Berzelius and the first organosilicon chemicals had been synthesized by Friedel and Crafts around 1863. Research done by Prof. F. S. Kipping in England around the turn of the century laid the foundations of silicone chemistry as we know it today, but it remained for General Electric Co. and Corning Glass Works chemists, working in the 1930's, to refine techniques and make the production of organosilicon compounds commercially feasible.

The silicones form a group of synthetic materials whose chemical structure contains both organic and inorganic linkages to produce many of the most desirable properties of both. Silicones exist in a wide range of physical forms from simple mobile fluids, through greases and flexible rubbers, to hard, durable resins of complex structure.

The unique properties of silicones have qualified them for many applications in almost all major industries. Some of the more important applications for the different classifications of silicones are shown in Fig. 1, p. 151. Uses such as cosmetics or automobile polishes, while important, are not directly of interest to the plastics industry. As a class, the silicones have the following outstanding properties: 1) stability to high temperatures; 2) retention of properties at extremely low temperatures; 3) resistance to weathering and oxidation; 4) good dielectric properties; 5) durable water repellency; and 6) chemical inertness. While most silicones show outstanding abhesive properties and are used in release applications, some are excellent adhesives for most materials.

Structure

The term silicone is generic for all organopolysiloxanes. Structurally, organopolysiloxanes are compounds containing a skeleton of alternating silicon and oxygen atoms with organic groups also attached to the silicon.

Physical properties of the silicones depend upon the nature of the organic groups, the ratio of organic groups to silicon atoms, the molecular weight, and the detailed molecular architecture. Silicones may be linear, branched, or cross-linked. Dependent on these factors, a silicone may be a fluid, elastomer, or thermoset resin.

Manufacturing processes

Regardless of physical form, most silicone polymers are produced by the hydrolysis and condensation of organosilicon halide intermediates. The intermediates may be produced by various methods. Simplified examples are shown on facing page.

The direct process, involving the reaction of methyl chloride and silicon metal to produce methylchlorosilanes, is the simplest process for producing methylsilicones in high yield. Phen-

*Manager, Technical Service, Silicone Products Dept., General Electric Co., Waterford, N. Y.
Recent Developments and References were prepared by the editors.

ylchlorosilanes can be produced by any of the aforementioned methods.

The familiar principles of organic polymer chemistry also apply to the design and production of silicone polymers. Thus, silicone fluids are short-chain polymers whose molecular weight is controlled by the amount of monofunctional units included in the condensation as chain stoppers. Elastomers are linear polymers of high molecular weight that are capable of vulcanization after compounding with reinforcing fillers. Resins are produced in a reactive "B-stage," by partial condensation of di- and trifunctional monomers. They are cured by heat and catalysts.

Because of the wide variety of silicone polymers and their many applications, it is impossible to describe all of the processing and fabricating techniques. Here again the processes used on organic polymers apply and, in general, conventional processing equipment can be used although high curing temperatures may be required.

Silicone fluids may be emulsified in water by conventional techniques to provide stable, aqueous emulsions. Compounding with finely divided fillers or stable soaps yields greaselike compounds.

Resin solutions may be milled with pigments in the same manner as organic resins to formulate paints and enamels. Alternatively, they may be combined with fibrous fillers for molding or used as bonding agents for glass cloth for laminating.

Elastomers are compounded with a wide variety of reinforcing fillers and vulcanizing agents in conventional compounding equipment to yield silicone rubbers of almost any desired combination of properties.

Silicone rubbers

The commercial availability of silicone rubber has given the design engineer materials that provide the peculiar properties of rubber under conditions not before possible. The major features of silicone rubber distinquishing it from other elastomers are:

1) Resistance to temperature extremes far beyond the limits of all other known rubbers (—150 to 600° F.).

2) Superior resistance to compression set throughout its entire useful temperature range.

3) Unequaled resistance to ozone, aging, and sunlight.

4) Good chemical resistance, making it odorless, tasteless, noncorrosive, nonstaining, and nonsticking.

5) Good electrical properties which are maintained at elevated temperatures.

Silicone rubber materials are available in consistencies for molding, calendering, caulking, sponging, laminating, and wire covering. Dispersions are also available for coating operations.

While all silicone rubber compounds in general possess the features outlined above, the rapidly expanding technology has made possible the classification of the many available recipes according to predominant properties. Presently available silicone elastomers fall into one or more of the following classifications: 1) general purpose; 2) low compression set; 3) extreme low temperature; 4) extreme high temperature; 5) wire and cable; and 6) pastes. The first four classes are based on cured physical properties while the last two are based on processing requirements. The property differences upon which the first four classes are based are outlined in Table I, p. 150.

The fabricator of silicone rubber components has commercially available to him raw silicone rubber compositions in each of these classes. In addition he has available pure silicone gum polymers of various types that may be compounded into the desired type of composition. The silicone polymer determines the basic classification while other compounding components, such as fillers, curing agents, and additives, determine characteristics such as the degree of reinforcement and processability.

The characteristics of silicone rubber and the variety of types processable by practically any technique standard for the rubber industry have dictated their use in an amazing variety of commercial applications. The major application categories are outlined below:

Aircraft industry: Various airframe applications take advantage of the low-temperature flexibility. Engine components take advantage of high-temperature compression set and resistance to various fluids.

Appliance industry: Advantage is taken of high-temperature compression set and maintenance of good electrical characteristics over a wide range of temperatures.

Electrical industry: Silicone rubber meets the requirement for extruded insulation and insulation tape, both supported and unsupported. Silicone rubber also finds use in many molded and ex-

truded parts, included among which are such items as bushings, seals, and spacers.

Miscellaneous: Other applications range from nursing bottle nipples to parts for handling hot glass. In these applications advantage is taken of the general inertness to the effects of extremely high temperatures and exposure to many assorted media.

Molding compounds

High-impact, glass-filled silicone molding compounds are adaptable to compression or transfer molding. Molded parts have a heat distortion point greater than 900° F. and retain exceptionally good physical and electrical properties in service at temperatures well above 400° F. At 400° F., for example, the flexural strength is 6000 p.s.i. and the compressive strength is 4000 p.s.i.

Laminating resins

Silicone laminating resins are ordinarily used with glass fabrics because the finished laminates are intended for high-temperature operation. Resins are available for either high-pressure or low-pressure fabrication techniques. Silicone laminates have exceptional high-temperature stability and retain a much higher percentage of their room-temperature strength at elevated temperatures. They are characterized by excellent electrical properties even after prolonged immersion in water or at elevated temperatures.

Low-pressure laminates have flexural strengths of 30,000 to 50,000 p.s.i. at room temperature, 15,000 to 20,000 p.s.i. at 500° F; dissipation factor after 24 hr. immersion in water is about 0.0008 at 10^5 cycles.

High-pressure laminates retain dielectric strength of 400 v./mil after 5000 hr. at 500° F., and a dissipation factor of 0.044 at 10^5 cycles after 24 hr. immersion in water. Flexural strength at room temperature is in the range of 24,000 p.s.i.; at 500° F., the flexural strength is approximately 4500 p.s.i.

Foam resins

Ready-to-use foaming powders require no mixing nor addition of catalyst or blowing agent. They expand on heating at moderate temperatures to produce rigid, low-density, nonflammable foam structures with a heat distortion temperature of 700° F. Thermal conductivity is 0.3 B.t.u./hr./sq. ft./° F. for 1-in. thickness. Water absorption, after 24-hr. immersion, ranges from 2 to 4 percent. Weight loss, after 1000 hr. at 500° F. is less than 4 percent. Good dielectric properties are retained in service at elevated temperatures.

Release agents

Silicone release agents are available as 100% silicone fluids, as water-dilutable emulsions, as greases, or as solvent solutions. They are chemically inert and heat stable; therefore, there is no chemical attack on molds or molded parts and no carbonaceous build-up of release agent on molds. Because of their low surface tension they give rapid, complete mold coverage, and because of their low volatility they reduce smoking and stay in place.

Silicone release agents provide better-appearing parts, both in surface finish and detail, longer mold life, and lower mold clean-out and maintenance costs. They are used on compression, injection, and transfer molds, extrusion dies, laminating plates or forms, and embossing rolls. They are also used in release of glass and metal castings.

Lubricants

Silicone lubricants are available either as fluids or greases which cover an operating range from —100 to 450° F. They offer product designers the opportunity of creating new equipment of improved performance, using designs previously considered impossible because of the limitations of conventional lubricants. They substantially reduce maintenance and relubrication costs.

Applications for silicone lubricants include rotating electrical equipment (motors, generators, etc.) designed for high- or low-temperature use, clocks or timers, conveyor systems, and others.

Outstanding properties include thermal stability (over 500 hr. at 400° F. in air without gelation), low viscosity-temperature coefficient, excellent stability to oxidation, and low volatility (less than 1% weight loss in 3 hr. at 200° C).

Silicone greases, in addition to lubrication uses, are used as dielectric compounds and mold release agents.

Adhesives

Silicone adhesives are used where excellent adhesion is required coupled with such inherent properties of silicones as unusually high moisture resistance, thermal stability, low-temperature flexibility, chemical inertness, and resistance to aging.

Silicone adhesives may be used in conventional bonding operations or as pressure-sensitive adhesives on tapes or fibers. Such pressure-sensitive adhesives remain tacky and flexible from —80 to 500° F., and they retain good adhesive properties for long periods at high temperatures. They provide excellent bonds to such materials as metals, glass, paper, silicone rubber, and plastics, including such difficult-to-bond materials as Teflon and polyethylene.

When a suitable backing is used, silicone pressure-sensitive tapes combine good dielectric properties with resistance to thermal aging and to moisture. They are used in a wide variety of electrical and electronic applications, as well as

TABLE I: Properties of classes of silicone elastomers

Class	*Durometer range*	*Tensile strength range*	*Elongation range*	*Typical comp. set, 22 hr. at 300° F.*	*Min. useful temp.*	*Min. useful temp.*

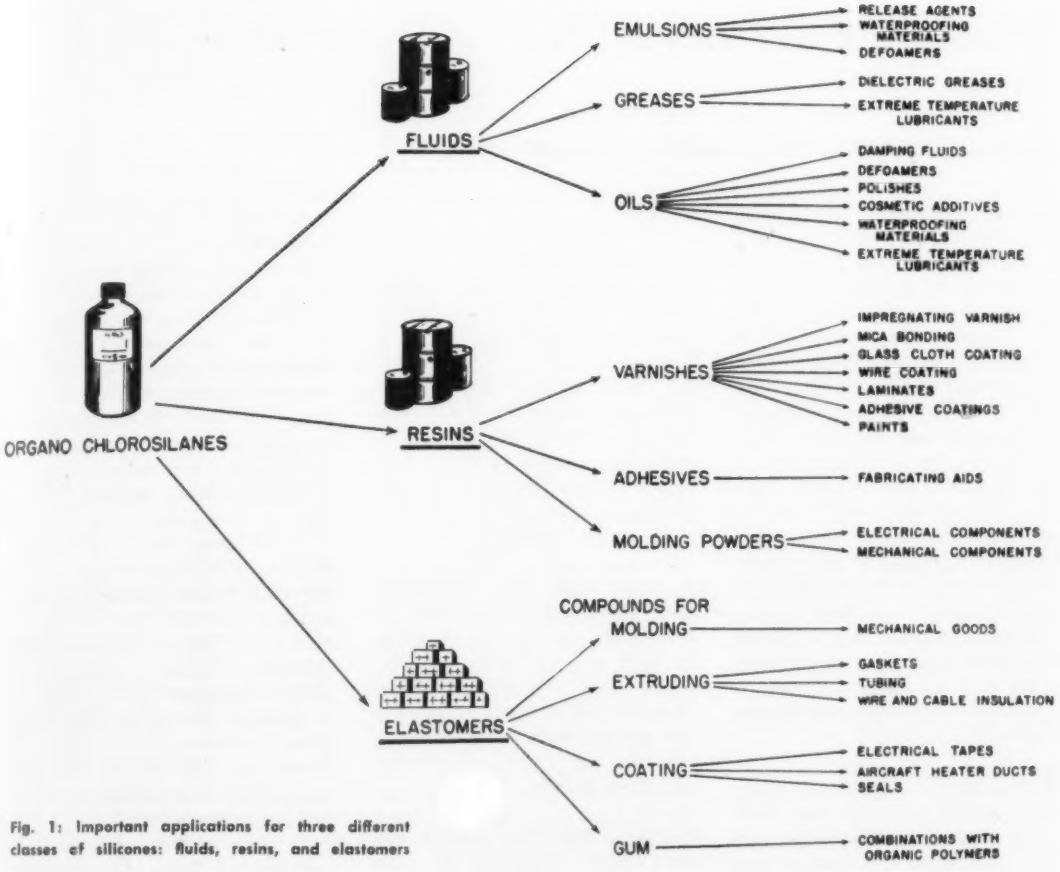

Fig. 1: Important applications for three different classes of silicones: fluids, resins, and elastomers

in mechanical applications where resistance to heat, moisture, or weather is important.

Miscellaneous

Silicone resins, used in combination with inorganic materials such as glass, mica, and asbestos provide operation of electrical equipment at Class H temperatures with a permissible continuous "hot spot" of 180° C. Much Class H insulation will withstand long service at 250° C. Electrical applications for silicone resins include their use as dipping and impregnating varnishes, mica-bonding resins, saturants for glass-served wire, cloth-coating resins, and water repellents.

Under the same operating conditions silicone Class H insulation has a service life many times as long as Class B (135° C. hot spot) insulation and provides greatly increased overload capacity.

Silicones are among the most effective and versatile defoaming agents available, and silicone antifoams have found applications in many parts of the plastics industry. For example, silicone antifoams are used to suppress foaming during stripping of resin or rubber latices after polymerization, and to prevent the inclusion of foam in latex articles.

The addition of small quantities of silicone fluids to plastisol formulations has been reported to reduce blocking and improve the surface slip of finished items.

Styrene Polymers and Copolymers

RECENT DEVELOPMENTS

A styrene-acrylonitrile copolymer (*Polyflex 230*, Plax Corp.), which is biaxially oriented by unique extrusion methods, is available in standard width sheets of 21 and 42 in. and gages from 0.003 to 0.020 inch. The biaxial orientation of this material imparts toughness and provides for long life and economy in thin film form. It is unaffected by temperatures as high as 185° F. and as low as −60° F. It is virtually unaffected by ultra-violet from sunlight and although it transmits infra-red rays, it holds back "earth radiation" in the 40° to 150° F. range. It is recommended for use in greenhouse construction, in storm window manufacture, and wherever a low-cost outdoor-weathering plastic film is needed.

A medium-impact styrene molding material (*Lustrex LHA Natural*, Monsanto Chemical Co.) was developed for applications which require greater impact strength than general-purpose styrenes can offer and greater clarity than is possible with the high-impact styrenes. In the packaging field where clarity and toughness are equally important, this material provides an optimum combination of physical properties.

Solid-solution plastic fluors (Cadillac Plastic & Chemical Co.) for use in scintillation counters are cast alloys of polystyrene with small percentages of *p*-terphenyl and tetraphenylbutadiene. The fluors are available in rod form in diameters from 3 to 18 in. and in lengths up to 3 feet. They are said to be superior to the commonly used crystal phosphors in hardness, machinability, and chemical stability.

A high-impact, styrene-type molding compound (*TMD-5161*, Bakelite) has a heat distortion point in the range of 190 to 195° F. It is designed for electrical appliance housings that must withstand rough handling.

A new grade of high-impact polystyrene material (*Super 44*, Kleestron, Ltd.), for injection molding and extrusion, has improved flexibility and resistance to shock, allows molding in thinner sections with fewer supporting ribs, and permits undercuts and deep draws.

A polystyrene-cased storage battery (Exide Industrial Div., The Electric Storage Battery Co.) for emergency lighting has been approved by Underwriters Laboratories, Inc. Previously U/L accepted storage batteries only if encased in glass or opaque vulcanized rubber.

Extruded styrene copolymer sheet (Campco Div., Chicago Molded Products) has improved strength and color and can be obtained in sizes up to 3/16 in. thick. It is free from internal strain and can be readily formed into complex shapes and deep draws. It may be used for automotive applications.

While polystyrene was discovered in 1839, it was not produced commercially until 1935. Since its rise in commercial availability and popularity, many improvements have been made in the properties of the material.

Styrene monomer is the principal raw material from which styrene polymers and copolymers are made. Styrene may be polymerized alone or it may be copolymerized with other monomers by bulk, suspension, emulsion, or solution processes.

Molding: Advanced techniques in these polymerization processes and in compounding have resulted in the development of a broad range of styrene materials for molding. Each of these materials offers a specific combination of physical properties and behavior characteristics that enable it to be used economically for producing parts to satisfy specialized service requirements in certain areas of use. Heat-resistance, chemical-resistance, toughness, stability, etc., will vary among the various available styrene materials.

In addition, styrene materials are available with various combinations of flow and set characteristics suitable for optimum molding of parts according to wall thickness. When selecting the grade of styrene to be used for a specific job, the molder must take into account this balance of "flow" and "set" attributes, with wall thickness generally affecting the choice as follows:

1) Thin sections (up to approximately 0.045 in.)—Flow to be emphasized (particularly for large-area moldings) with sacrifice in set. Short heat travel path and cold molds minimize cooling time.

2) Medium sections (0.045 to 0.075 in.)—Compromise of good flow and good set.

3) Heavy sections or mixed thick and thin sections—Fast or high-temperature set to be emphasized with flow more or less sacrificed.

Extrusion: Diversification of styrene extrusion materials has not developed to the same extent as in the styrene molding materials. Most extruded products are made from a distinct "extrusion grade" (usually without surface lubricant) in each class of polymer or compound. In the fast-growing field of sheet extrusion with rubber-modified compounds, the beginnings of a trend toward

Recent Developments and References were prepared by the editors.

more specialized compounds can be detected in the appearance of separate compounds emphasizing gloss, toughness, or enhanced output rates.

Types of styrene

Among the classes of styrene polymers, copolymers, and compounds are: 1) general-purpose (or polystyrenes and polystyrene compounds); 2) heat-resistant; 3) light-stabilized; 4) glass-reinforced molding compounds; 5) impact types (or rubber-modified polystyrene compounds, styrene-rubber plastics, etc.); 6) chemical-resistant copolymers (or styrene - acrylonitrile copolymers); and 7) polymers and copolymers of alkyl-substituted styrenes. (All of these polymers are available in pellet or granule form and with various internal and/or external lubrication agents best suited to the product-forming process and equipment to be used.) Special processing techniques and compositions have also made the following added forms of styrene available: 8) oriented polystyrene and styrene-acrylonitrile copolymers; and 9) expandable and expanded polystyrene foams.

General-purpose polystyrenes

Actually, in view of the diverse range of polystyrenes and polystyrene compounds now available, the description "general-purpose" has become a misnomer. The term, however, still persists and is widely used.

Many outstanding features are responsible for making polystyrene one of the most popular of plastics. It is the lightest in unit weight of present commercially available rigid plastics. Because the basic resin is colorless, the polymer can be made crystal clear or in an unlimited range of colors —from transparent to opaque. Excellent dimensional stability combined with negligible moisture absorption (even after long-term immersion) and freedom from warping or distortion within the thermal operating range of each grade make the polystyrenes useful where molding to close tolerances is required.

Polystyrene is free from taste and odor, nontoxic when used in contact with food, and does not support growth of molds or fungi. Its resistance to corrosive chemicals and their aqueous solutions, such as acids (except oxidizing acids), alkalies, salts, and lower alcohols is outstanding. Electrical properties are exceptionally good over the whole range of frequencies in practical use.

Applications: Disposable packaging for all sorts of merchandise, along with dispensing dishes and utensils for foods, are the fastest-growing high-volume uses for polystyrene. Refrigerator parts (e.g. crisper trays, meat keepers, butter dishes, etc.,), emblems, signs and displays, and packaging applications of a more permanent nature all use polystyrene because of its physical advantages as well as the fact that it lends itself so well to decoration. Decalcomania, hot-stamping, wipe-in painting, metalizing, lacquering, and silk screen printing techniques have all been adapted to polystyrene. Toys, game pieces, novelties, combs, brush-backs, wall tile, many housewares for use with cool foods, flower pots, and planters are all made advantageously from polystyrene. Special compounds are used in phonograph records.

Heat-resistant polystyrenes

For satisfactory service in high-temperature atmospheres, e.g. in heavily-illuminated display windows or cases or in closed automobiles kept out in the hot summer sun, heat-resistant polystyrenes have proved themselves over the past nine years. Parts molded of heat-resistant polystyrene show good retention of dimensional stability in boiling water, but cannot really be called "boilable." Coincident with improved heat resistance, these grades have enhanced physical properties that often dictate their use even where heat resistance is not in question.

As contrasted to easy-flow materials, the heat-resistant polymers reach moldable plasticity and set up in molds at higher temperatures. This behavior makes molding machines with plasticating capacity and good mold temperature control in the range of 130 to 180° F. necessary for quality economical production. To realize the full potential in strength and heat resistance, however, annealing may be required in some cases. Slow cooling after annealing prevents introduction of new thermal stresses.

However, annealing only increases the heat distortion of a piece when measured under load such as by the A.S.T.M. test. It does not appreciably improve use temperature when the distortion of a piece due to shrinkage or other stress relaxation is the determining factor, as it is in many applications.

Under some circumstances, it is possible to run faster molding cycles with these heat-resistant grades than with normal polystyrenes. Because set-up is so rapid, these grades are especially adaptable to the molding of heavy sections. Because of their high-strength characteristics, heat-resistant grades are also often preferred for the extrusion of rods, tubes, profiles, wall coverings, etc.

Applications: With the same coloring and decorating potential as normal polystyrenes, the heat-resistant polystyrenes have been extensively used in table model radio cabinets, TV lenses or front panels, clock cases, watch and jewelry packages, storage battery cases, camera housings, appliance panels and handles, illuminated signs and displays, fluorescent lighting fixtures, housewares to withstand unusual stress or hot food contact, and reels and spools for film and tapes.

Light-stable polystyrenes

Normal polystyrenes do not resist outdoor weathering sufficiently to warrant use in permanent outdoor installations. Exposure to ultra-violet light from direct sunlight or artificial sources causes polystyrenes to develop a yellowish straw cast and eventually become brittle. Light-stable formulations, which, by test under ultra-violet light sources, show substantial improvement in such behavior, have therefore been developed. However, the degree of stability is not so great that stabilized polystyrenes can be recommended for outdoor uses. On the other hand, light-stable

polystyrenes are finding increasing use in molded and extruded indoor lighting fixture diffusers and in packaging to protect contents from discoloration or spoilage from ultra-violet light exposures. In some cases, improved light stability is achieved with some sacrifice of heat resistance or strength characteristics. In other instances, the light-stabilized formulations are slightly limited in colorability, making it difficult, for example, to produce clean translucent bluish-white.

Although initially slightly yellow, styrene-acrylonitrile copolymers show less change upon exposure to light than do the normal polystyrenes.

Glass-reinforced polystyrenes

Fibrous glass-reinforced polystyrene is made for the production of strong, rigid pieces with superior dimensional stability. The normal method of manufacture is by injection molding. Compression molding or extrusion techniques ordinarily do not result in the entanglement and felting of the glass fibers which is necessary to realize the full reinforcing potential of the fibers. Compounds usually contain about 35% glass by weight; some have been made up to 50 percent. The 35% compounds typically have heat distortion temperatures in excess of 215° F., tensile strengths about 10,000 p.s.i., and mold shrinkage of only 0.001 in. per inch.

Glass-reinforced polystyrenes are either supplied in slightly translucent to opaque colors or in an off-white natural that may be dry-colored by the molder. Some decorative value can be achieved by mixing these polystyrenes with transparent, heat-resistant polystyrenes. Service or appearance requirements of certain applications may be satisfied by mixing the glass-reinforced polystyrene pellets with heat-resistant polystyrenes or heat-resistant rubber-modified compounds to reduce the glass content.

Applications: Typical applications which take advantage of the toughness, rigidity, and the superior heat resistance of glass-reinforced polystyrenes are: tape reels, blower wheels, textile bobbins, housings, and military devices that have to be able to withstand rough usage.

Light-stable polystyrenes are finding increasing use in molded diffusing pans for fluorescent fixtures. (Photo, Sheffield)

Impact-type polystyrenes

With the rise in popularity of polystyrene and the widening of its markets, it soon became evident that the toughness of normal polystyrenes was inadequate for successful use in some fields. Research resulted in so-called "impact polystyrenes," or rubber-modified compounds. These materials are characterized by improved shock resistance and increased elongation, while still retaining good electrical and mechanical properties.

There are three general classes of products in this category—medium-, high-, and super-impact materials—with increasing shock resistance or toughness shown in each classification. As with normal polystyrenes, impact materials are available with various combinations of flow and set characteristics suitable for optimum molding of parts according to wall thickness. Other compounds combine improved heat resistance and strength with the toughness imparted by the rubber content. Thus, selection of a rubber-modified polystyrene can be made with an eye to service requirements and economy.

As a consequence of increased elongation and impact properties, the high-impact polystyrenes can be molded around metal inserts without later development of crazing or cracking. These improvements also permit machining and drilling of parts without the use of some of the precautions necessary with normal polystyrenes. The high-impact materials may also be punched on automatic machines, which is not possible with normal polystyrenes. Annealing is seldom required.

Impact materials are naturally translucent, limiting colorability to translucents and opaques. They are normally supplied as pellets, but granules or "fine grinds" are available in natural for dry-coloring. Compounds are usually externally lubricated for molding, unlubricated for extrusion.

Special high shock-resistant extrusion compounds specifically suited to the growing sheet markets are also available. These sheets are extruded in thicknesses from 0.010 to 0.250 in. and widths up to 60 inches. Extruded sheet is generally used for the thermoforming of large refrigerator parts and advertising displays requiring detailed features. Extruded striated sheet is used for decorative wall covering.

Applications: Successful applications for rubber-modified polystyrenes include toys, novelties, signs, and displays; radio cabinets, television masks, small appliance handles, and knobs; refrigerator and freezer door liners, spacers, trim strips, pans, and bins; air conditioner panels and grilles; disposable packaging, closures, food and drink dispensing dishes, and utensils; housewares, furniture drawers, and wall coverings; storage battery cases, tote boxes, shipping trays, and housings.

Chemical-resistant styrene copolymers

Many common household and industrial articles must withstand contact with substances that attack polystyrenes, such as aromatic, aliphatic, and chlorinated hydrocarbons, organic acids and esters, essential oils, and fats. To meet this need, copolymers of styrene and acrylonitrile have been developed.

In many of the uses for this type of resin, the mechanical properties are more important than the chemical resistance. While not a high-impact resin, its mechanical properties are

superior to ordinary polystyrene. This results in greater practical toughness, which, combined with clarity, accounts for many of the uses of the styrene-acrylonitrile resins. While the chemical resistance of the styrene-acrylonitrile copolymers is dependent only on the acrylonitrile content, the mechanical properties are better for the higher-molecular-weight resins at some sacrifice in molding plasticity. Thus, among the styrene-acrylonitrile resins available commercially, there are significant differences in their practical toughness under use conditions. Pieces injection molded from all polystyrenes are weaker when stressed parallel to the lines of orientation than when stressed across the orientation. But in styrene-acrylonitrile copolymers, this difference is less than for polystyrene, resulting in stronger pieces when stressed across the orientation. Usually, electrical properties and water absorption are slightly impaired, as compared to normal polystyrenes.

Pelleted injection and extrusion grades of these materials are supplied. Natural styrene copolymer resin is a pale straw color; transparent tints to opaque colors are also available. These copolymers are incompatible with polystyrene and its compounds.

Applications: Principal uses are housewares (dishes, tumblers, and cutlery handles); hair curler pins and cosmetic packaging; fountain pen barrels; battery cases and radio cabinets; sight glasses for pressure oil systems and oil dispensing devices; and laboratory utensils.

Polymers and copolymers of alkyl-substituted styrenes

Certain homologues of styrene have been known for many years to form polymers with notably higher heat distortion temperatures than are attainable from styrene itself. However, use of any higher-molecular-weight monomer does not guarantee this result. Commercialization in this area has been impeded by the unavailability of suitable low-cost monomers and their generally slower polymerization rates. Alpha-methyl styrene and specific mixtures of o-, p-methylstyrene (vinyltoluenes) are the first of these monomers to become available at low cost. A methylstyrene polymer and its copolymer with acrylonitrile, announced in 1956, was undergoing trade introduction and evaluation during scale-up to production capacity during 1957. In general, these can be expected to find a place in applications similar to those now satisfied by older heat-resistant polystyrenes or chemical-resistant copolymers, but where the service temperature is expected to be exceptionally high, or an added measure of toughness is desired.

Oriented polystyrene

When stretched in the fluxed state while cooling, polystyrene develops increased strength up to three-fold in the direction of stretch. Uni-directionally oriented polystyrene and chemical-resistant copolymer filaments are widely used as bristles for brooms and dusters as well as scrub brushes, utility brushes, and even inexpensive tooth brushes. When dry, the static charges developed by the brushing operation assist in causing lint and dust to adhere to the bristles. The adhesion, however, is not so strong that particles cannot be readily shaken or rinsed off.

Bi-directionally oriented polystyrene film is produced by stretching the fluxed plastic simultaneously laterally and longitudinally. The film can be as thin as 0.005 in., used chiefly for electrical capacitors. Film of 0.001-in. thickness is used for laminating to impact-type polystyrene sheet to retain gloss after vacuum forming. Oriented polystyrene of 0.015-in. thickness is used to form Venetian blind slats. Intermediate thicknesses are finding wide application in the packaging and luminous ceilings fields as well as in coaxial cable spacer wrap. A biaxially oriented styrene-acrylonitrile copolymer film for greenhouse construction, storm windows, etc., is also available.

Polystyrene foams

Polystyrene foams are available in two types—free-flowing granules which are expanded in place, and logs or planks from which shapes are machined. Both types of foam are available at densities below 2.0 lb./cu. foot. Both exhibit very low water-vapor transmission, low water absorption, low thermal conductivity, and good structural strength. Expanded polystyrene may be bonded to itself as well as to metals, glass, wood, and other solids. Polystyrene foam can be shaped by common machining operations, such as sawing and drilling.

Styrene Alloys

BY P. M. ELLIOT* and R. F. McCABE*

RECENT DEVELOPMENTS

Styrene - butadiene copolymer latex (*Dylex K-52,* Koppers Co., Inc.) is available for coating of printing paper. The latex has good compatibility with starch, dextrin, and protein adhesives. It may be used alone or in combination with natural adhesives and clays to improve printability and ease coating problems.

An improved modified styrene resin in pellet form (*Plio-Tuf P100,* Goodyear Tire & Rubber Co., Chemical Div.) can be injection molded and extruded with conventional equipment. Its uniform size permits accurate metered feeding and promotes an even distribution of heat through the material. Items made of this resin have good stiffness and high-impact strength, even at low temperatures. They are essentially inert to chemical attack and have good resistance to high heat.

Styrene-butadiene resin (*Plio-Tuf,* Goodyear) is calendered into sheet (Charles Crowl Co.) for thermoforming such products as airplane and auto parts, machine covers, display panels, window frames, and refrigerator door liners. The toughness of the sheet resembles that of the super-impact modified styrenes. It runs faster on a calender than other rigid-type sheetings.

A 98-mile styrene alloy (*Kralastic,* Naugatuck Chemical) pipe line (Republic Steel Co.) has been installed in west Texas to carry fuel to 200 irrigation pumps. It is believed to be the longest of its kind in the country.

A new extrusion plant in Lubbock, Texas (United Pipe & Tube Co.), will extrude rigid polyvinyl chloride and styrene-butadiene-acrylonitrile pipe for use in oil fields and industrial plants, for water systems and gas distribution. Pipe sizes up to 12-in. dia. will be produced. Long-range plans include production of plastic-lined steel pipe.

Polyvinyl chloride can be blended with thermoplastic copolymers (*Cycolac* series, Marbon Chemical) containing acrylonitrile, butadiene, and styrene, to produce improved processing, increased heat resistance, and increased impact strength. Room temperature impact values exceeding 10 or 15 ft.-lb. are possible for blends containing approximately 50 parts of blending resin copolymer.

Polystyrene has come a long way since its commercial introduction in 1935. It was undoubtedly the wide consumer acceptance of this thermoplastic, despite its inherent deficiencies, which contributed greatly to the development of a unique series of hybrid thermoplastics that today are designated by the term "styrene alloys." To broaden the market for styrene-based resins, the drawbacks of brittleness and low heat distortion temperature had to be overcome.

Between 1944 and 1946 three resins that exhibited an improvement in heat distortion temperature over general-purpose polystyrene were commercially introduced. Polydichlorostyrene and the copolymers, styrene fumaronitrile and styrene divinylbenzene, ranged between 220 and 250° F. in heat distortion temperatures. But cost, poor moldability, and continued technical advances in the field of copolymers limited commercial acceptance of these resins.

In 1946 acrylonitrile was copolymerized with styrene and the copolymer met with wide industry acceptance. The advantages of this copolymer over polystyrene were its higher heat distortion temperature, somewhat improved impact strength, excellent weathering resistance, better chemical resistance, and higher flexural strength at elevated temperatures. Izod notched impact strengths were still under 1 ft.-lb./in. of notch, and it was recognized that greater improvements would be necessary.

Styrene and rubber

By 1948, a basically new principle in polymer chemistry demonstrated that suitable blends of the right resin and rubber would exhibit the hardness and high heat distortion of the resin and the toughness and low brittle point of the rubber.

Copolymerization of styrene with small amounts of butadiene produces tough, horny resins which the rubber industry has blended with GR-S type rubbers as reinforcing agents and processing aids. This development bordered on the plastics industry; when the resin ratio was high enough (over 60%), the blend assumed more the properties of a plastic than of an elastomer. Uncured, the high resin blends were limited in application because of low flexural strength and low heat distortion point. When vulcanized by usual rubber procedures, however, the composition forms a tough, rigid thermoset material. The softening point of typical cured blends was still between 130 and 140° F.

A second type rubber-resin blend commercialized in 1946 in the form of fabricated parts or sheet stock constituted a major advance in the field of high-impact materials. The discovery that styrene acrylonitrile copolymer resins could be blended with

* Naugatuck Chemical, Div. of United States Rubber Co., Naugatuck, Conn.
Recent Developments and References were prepared by the editors.

butadiene acrylonitrile rubbers made available a new series of styrene alloys possessing greater impact strength, higher heat distortion temperatures, improved chemical resistance, better weathering qualities, and good flexural strength. These materials are commonly known as acrylonitrile - butadiene - styrene polymer blends (ABS polymer blends).

Between 1949 and 1955 more than 15 styrene alloys were introduced commercially. These were based on blends of polystyrene and/or styrene-butadiene copolymers of varying ratios. When alloyed with high-styrene low-butadiene copolymers, polystyrene yields high impact, high flexural strength thermoplastics. A number of variations of this alloy are possible since two ratios exist—styrene to butadiene and polystyrene to styrene-butadiene copolymer.

Property variations depend largely on the resin/rubber ratio. In addition to high impact strength and flexural strength, this type of styrene alloy may possess greater ultimate elongation and lower brittle point than polystyrene. Due to the internal plasticizing effect of the butadiene, it is handicapped by softening points lower than those of polystyrene. Low cost, good moldability, and medium-to-high impact strengths have, however, resulted in widespread commercial acceptance.

A new series of molding powders offered commercially in 1949, based on a copolymer blend of styrene-acrylonitrile and butadiene-acrylonitrile, was similar in properties to the blends introduced earlier in the form of fabricated parts or sheet stock. A wide range of physical and chemical properties was possible by adjusting the proportion of styrene to acrylonitrile in the resins and of butadiene to acrylonitrile in the rubber, as well as by varying the ratio of resin-to-rubber in the final alloy blend. Selected numbers of this series of alloys have been made commercially available.

Another combination of butadiene, styrene, and acrylonitrile reported by the manufacturer to be a "homogeneous" composition was introduced in late 1953. It combines high hardness with impact over a wide temperature range, good processing qualities, high heat resistance, and excellent chemical resistance.

Chemistry and manufacture

Styrene monomer is generally produced by catalytic dehydrogenation of ethylbenzene which is obtained by reaction of benzene with ethylene. Styrene is also produced by the reaction of benzene with acetylene.

Polymerization of styrene, or copolymerization with a variety of other monomers including butadiene and acrylonitrile may be accomplished by bulk, suspension, emulsion, and solution polymerization techniques.

Recent developments in techniques such as series, graft, and block polymerization are regarded as major advances in the art. Styrene alloys produced by use of these techniques reportedly offer greater ease in processibility and relatively high impact strengths at low temperatures (—40° F.).

In the production of styrene alloys, latex blending and Banbury-mill mixing are used with equal success. Latex blending, as the name implies, involves the blending of polymer or copolymer latices. Coflocculation of the latices by the addition of sulfuric, lactic, or formic acid or other flocculating agents results in a resinous crumb which is filtered and washed to remove soluble residue. When dried, this masterbatch may be compounded with other ingredients by Banbury, mill, extruder, or other mixers.

Injection molding

The styrene alloys are well suited to injection molding, and can be readily handled on standard machines. Most manufacturers recommend predrying granules at 160 to 200° F. for a period ranging from 45 to 90 min. or longer. The use of hopper driers or preplasticators is frequently recommended. Predrying and preheating eliminate the possibility of absorbed water affecting the molding surface, increase capacity since they permit the injection heating cylinder to heat a greater volume of material per hour, and improve quality by permitting the use of lower but more uniform material temperatures.

Cycle, temperature, and pressure used in molding styrene alloys depend on the pieces being molded, the specific alloy being used, the geometry of the die, and the machine itself. Styrene alloys are readily adapted to both heavy and thin section moldings.

Materials manufacturers recommend cylinder temperatures in the range of 300 to 550° F., die temperatures in the range from 130 to 200° F. Some manufacturers recommend the use of nozzle heaters to insure maximum alloy flow properties in the die.

Extrusion and calendering

Styrene alloys may be handled easily in standard extrusion equipment to produce pipe, tubes, rods, and profiles. The rubber content of most styrene alloys is such that in extrusion it does not approach the near-Newtonian flow characteristics of some thermoplastics.

Predrying is generally recommended. Cylinder and die temperatures vary depending on the rubber content of the blends, but roughly they range between 390 and 450° F. Clearance between the screw and cylinder wall should be small, ranging between 0.003 and 0.005 inch.

Most manufacturers report best results when a torpedo head screw, Dulmage mixing screw, or nylon metering screw is employed. A compression ratio of 3:1 to 6:1 is recommended for maximum heating and mixing results. Screen packs are used with most alloys, usually two No. 40 or No. 60 with one No. 20, to promote a degree of back pressure and greater mixing. Streamlined die lands are recommended, ranging in length from the O.D. of the extruded shape to four times the O.D. or largest cross-section.

Cooling equipment and capstans of the conventional types may be employed. Draw-down recommendations vary with different alloys and also with type of sizing equipment. Some sys-

tems require die dimensions close to that of the extruded part; others use die dimensions 10 to 15% oversize.

Extrusion of sheeting is readily accomplished with certain alloys. Flat sheeting dies are most common for styrene alloys. Cylinder temperature recommendations range from 350 to 425° F., and flat die temperatures recommended are slightly lower depending on the alloy. Biaxial stretching by the use of clamps at the die opening has been found to improve physical properties of extruded sheets. Most styrene alloys are rigid or semirigid on cooling, and are cut in desired lengths for finishing.

Certain of the more resinous alloys may readily be calendered into sheeting 0.015 to 0.090 in. thick with excellent results. It is recommended that the alloy be worked on a mill at temperatures between 300 to 400° F., and fed in small slugs to the calender. On four-roll calenders, of the Z or inverted L types, forming roll temperatures usually range between 280 and 380° F. with the bottom roll slightly cooler. Sharp reproduction of detail is reported with certain of the alloys when an engraved calender roll is employed. Embossing may also be accomplished by setting embossing rolls next to the bottom calender roll.

Properties and applications

The variety of styrene alloys commercially available offers the plastics fabricator a wide range of properties. Some of the more important properties of commercially-available styrene alloys are outstanding impact strength, ranging up to 11 ft.-lb./in. of notch; high heat distortion temperatures, ranging up to 210° F.; a range of hardnesses, Rockwell R50 to R110; low brittle point of −40 to −60° F.; excellent chemical resistance; good mechanical properties; and good molding and extrusion characteristics. See Table I, below.

Injection molders have recognized that the higher unit cost of some of the alloys is more than offset by their unique toughness and high heat distortion temperatures. Appearance of the finished molded articles is excellent, and a range of colors is available.

Continued development of injection press preplasticators and larger machines with greater injection speeds will increase the number of functional and decorative applications for which the styrene alloys are used. Some of the present outstanding applications for injection molded alloys are in pipe fittings, wheels, helmets, valve parts, golf club heads, refrigerator parts, bobbins, radio cabinets, electric fan blades, toys, battery cases, and appliances.

Extruded acrylonitrile copolymer blend pipe, mainly because of its unique toughness and corrosion resistance, has substantially advanced the position of plastic pipe in a number of important applications. This pipe is widely used by the petroleum industry where piping is subject to extraordinary corrosion by brine and sour crudes, as well as in natural gas pipe lines, mine drainage systems, and irrigation applications. Paper mills, sewage disposal plants, water treating plants, heavy and fine chemical plants, textile plants, and food handling plants have all reported lower maintenance and replacement costs after installing these versatile piping materials.

Styrene alloy sheeting, extruded or calendered, is available in a wide assortment of colors and finishes. The rigidity and inherent toughness of this type of sheeting has led to its use in such outstanding applications as industrial duct work, automobile headliners and kick plates, typewriter cases, refrigerator door liners, tote boxes, trays, and a variety of functional and/or decorative housings.

Synthetic Rubber and Rubber Derivatives

BY L. H. HOWLAND* and R. W. BROWN*

RECENT DEVELOPMENTS

An **improved tarpaulin material** (*Fairprene*, Du Pont Fabrics Div.) provides greatly increased abrasion resistance combined with lightness. The new tarpaulin consists of nylon fabric with an exterior coating of neoprene (Du Pont) and a coating of synthetic rubber (*Hypalon*) on the underside.

New resins for rubber reinforcing (*Cellobond*, British Resin Products, Ltd.) are readily dispersible with natural and nitrile rubbers at all loadings. Due to their initial thermoplastic nature, these cashew phenolic-type resins facilitate the processing of highly loaded stocks, at the same time reinforcing hardness and other physical characteristics.

An epoxy rubber compound (*Maraset No. 636*, Marblette Corp.) is used as a gasket and sealing compound as well as an encapsulating resin for electronic compounds. This material has a tensile strength of 2600 p.s.i., an elongation in percent of 200, a durometer (Shore A) of 50-60, and is said to have excellent recovery.

A series of vinyl-silicone rubber compounds (*K-1044R, K-1045R, K-1046R, K-1047R, K-1048R*, Silicones Div., Union Carbide & Carbon Corp.) meets the toughest aeronautical specifications for high-temperature applications. These rubbers have controlled reactivity, high tear, high elongation, tensile strength of over 800 p.s.i., low compression set, good oil resistance, low moisture absorption, and good dielectric properties. They are "preconditioned" to permit easy processing.

Butadiene-styrene (formerly GR-S) copolymers are the largest volume products among the synthetic rubbers. They comprise a varied group of solid polymers and latices ranging all the way from 100% polybutadiene to copolymers containing up to 50% bound styrene. Masterbatches are available containing oil, carbon black, or mixtures of the two, and latices are manufactured at solids contents ranging from about 25 to 60 percent. The most widely used polymers contain approximately 75% butadiene and 25% styrene. Lower levels of styrene give better low-temperature flexibility at some sacrifice in physical properties, while higher levels of styrene give more plastic and less rubbery copolymers. Above about 60% styrene content, resinous products, rather than elastomers, are obtained.

The GR-S polymers used during the war were produced by what is termed "hot" polymerization. It was later found that polymerization at lower temperatures gives appreciably better properties, particularly with respect to tensile strength, abrasion resistance, and flex cracking. As a result, recipes were developed to permit rapid polymerization at the lower temperatures and, today, about 80% is made by the "cold" process.

"Cold" rubber is prepared commercially at about 41° F., although experimental runs have been made at temperatures of 0° F. and below. It is made by emulsifying the butadiene and styrene in water with fatty acid or rosin soap and polymerizing in pressure vessels with agitation to form a stable water dispersion of the polymer (latex). An organic hydroperoxide is used as catalyst along with various activators which speed up the rate of polymerization. Long chain (C_{12}-C_{16}) mercaptans are used as chain transfer agents or modifiers to give the desired plasticity. These recipes readily give reaction times of 6 to 12 hr. at 41° F. Cold GR-S is normally carried to 60% conversion. The hot polymers are prepared in a similar manner, except that the reaction temperature is 122° F., and potassium persulfate is the catalyst. The reaction is stopped at about 72% conversion.

Unreacted monomers are removed by vaporization and recovered for future use. The latex is then coagulated by treatment with acid or alum to destroy the soap, along with other chemicals (salt, glue, etc.) to control the size of the lumps of coagulum. The coagulum is then washed, dried, and baled. Careful control of variables in production makes synthetic rubber of considerably greater uniformity than natural rubber.

Some polymers are produced with lower than normal amounts of mercaptan modifier to give tougher rubber, which is then mixed with an amount of low-cost petroleum oil (usually 25 to 40%) in sufficient quantities to soften the rubber-oil mixture to a normal plasticity. The product has the usual handling and vulcanizate properties of synthetic rubber but is considerably reduced in cost. Mixing of the oil is done while the rubber is still in the latex stage to avoid handling of the tough unplasticized polymer. In 1956 these oil masterbatches had grown to about 40% of the total production of butadiene-styrene rubber.

The butadiene-styrene polymers as a group are general-purpose rubbers of wide applicability. They are used in tires, mechanical goods, footwear, and al-

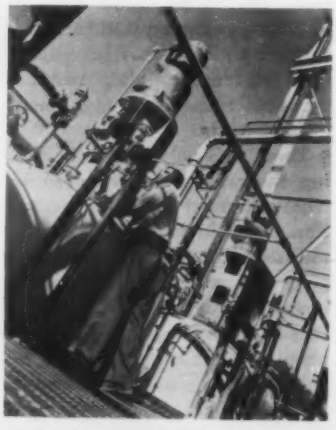
Recent Developments and References were prepared by the editors.

most all of the other places where natural rubber is satisfactory. One exception is in the carcasses of large truck tires, where their greater heat build-up during flexing makes the butadiene-styrene rubbers unsatisfactory. In the form of latex they are used for foamed sponge manufacture, rug backing, paper impregnation, and other applications. They have good aging qualities and are tough and resistant to heat and abrasion. Tire treads made from cold rubber show an increase in abrasion resistance of 15 to 25%, as compared to natural rubber.

As a class, the copolymers of this group develop much lower cured gum properties than natural rubber. Cured gum stocks of natural rubber range around 3500 p.s.i. whereas the GR-S polymers will fall far short of this range, showing less than 1000 p.s.i. However, by compounding properly with reinforcing pigments, resins, and plasticizers, stocks can be developed with tensile strengths almost comparable to those of natural rubber. On an over-all basis, the processing of GR-S can be controlled to a point at which special features can be "built into" the polymer so that processing is more adaptable and consistent than with natural rubber.



Butadiene-acrylonitrile copolymers

The butadiene-acrylonitrile copolymers (nitrile rubbers) are the same in general appearance and processing qualities as the butadiene-styrene copolymers. They contain various proportions of butadiene and acrylonitrile ranging from approximately 80/20 to 55/45. Manufacture is similar to the butadiene-styrene types, with a strong trend toward low-temperature polymerization. Their vulcanizates are characterized chiefly by high resistance to the swelling action of solvents, oils, and greases, and to deterioration by heat and sunlight. They are soluble in ketones such as acetone. These copolymers are also available as latices, which are useful for the impregnation and coating of many types of cloth, paper, and leather products.

The nitrile rubbers are cured with the same agents as natural rubber or GR-S, i.e., sulfur or sulfur-bearing materials. Again, as is the case with GR-S, the cured gum tensile strengths of nitriles are far below that of natural rubber, but with proper choice of compounding ingredients tensile strengths as high as 4000 p.s.i. can be obtained. One major change in the compounding of nitrile rubbers must be noted. Because of the oil-resistant nature of the basic polymer, many of the normal rubber plasticizers are ineffective. The ester-type oils and polar-type derivatives are the most effective.

Generally speaking, the same procedures can be employed when processing nitrile rubbers as are used with natural or styrene-type rubbers. However, the nitrile polymers require more critical milling and Banbury procedures. Ultimate dispersion of reinforcing pigments and curatives is more difficult. Building tack in these polymers is more of a problem than with the styrene polymers. In some cases, solvent activation of the rubber surface with a ketone solvent is necessary before it is possible to obtain building tack.

The chief advantage of the nitrile-type synthetic elastomers is their high resistance to the deteriorating and swelling effects of greases, oils, waxes, and solvents. Coupled with this advantage, the nitrile polymers can be compounded to be flexible at temperatures below —70° F. and to resist the deteriorating effects of high-temperature aging up to 300° F. The choice of the nitrile content is directly affected by the degree of oil resistance desired, and this increases as the nitrile content increases. However, as the nitrile content is raised, the copolymer loses in low-temperature characteristics.

Basic polymerization step in manufacture of synthetic rubber takes place in reactor vessel. (Photo, U. S. Rubber)

Some phenolic and vinyl resins, such as polyvinyl chloride, harden the nitrile rubbers, allowing a reduction in amount of mineral fillers. These resins also give compounds that are more resistant to the effect of solvents, high temperatures, and oxidation, and in some cases more fire-resistant. On the other hand, the addition of the nitrile rubbers to compounds containing predominant amounts of phenolics gives improved processing, impact resistance, and flexibility. In predominately polyvinyl chloride and related vinyl compounds, they act as nonvolatile, nonextractable plasticizers. Added to phenolic-resin cements the nitrile rubbers impart flexibility to the adhesive film, particularly at low temperatures.

Isobutylene-diolefin rubber

Butyl rubber is a copolymer of about 98 parts of isobutylene and 2 parts of isoprene. It differs from its nearest chemical neighbor, polyisobutylene (Vistanex), by being vulcanizable, a property imparted to it by the unsaturation of the copolymerized isoprene. This unsaturation, however, amounts to only about 3% of that normally occurring in natural rubber. This low degree of unsaturation is the major reason for the chemical inertness of butyl, upon which many of its uses depend.

Butyl rubber is prepared at very low temperatures (about —140° F.) by treatment of a solution of the monomers in methyl chloride with anhydrous aluminum chloride. The polymer forms as a slurry in the methyl chloride, from which it is recovered by treatment with hot water to vaporize the solvent and unreacted monomers.

Crude butyl resembles natural

rubber in appearance and handling properties. It is tacky, and tends to flow under its own weight. It is compounded and processed in the same manner and with the same machinery as is natural rubber or GR-S. With butyl, no breakdown or premastication is needed and its natural tackiness gives it excellent building characteristics. Softeners may be added to improve processing or special properties like resiliency or flexibility at low temperatures. Butyl is highly impermeable to gases. As a result, it has almost completely displaced natural rubber for inner-tube manufacture.

Aging- and temperature-resistance properties make butyl useful for fabricating curing bags which are employed in the vulcanization of tire casings and for the repairing of tires. Its good electrical properties coupled with its resistance to ozone make it well-suited for all grades of insulation. Furthermore, it has remarkable resistance to the chemical action of concentrated sulfuric, hydrochloric, hydrofluoric, and phosphoric acids, ferric chloride, caustic, and other corrosive substances. It finds special use as linings in tanks, pumps, and hoses.

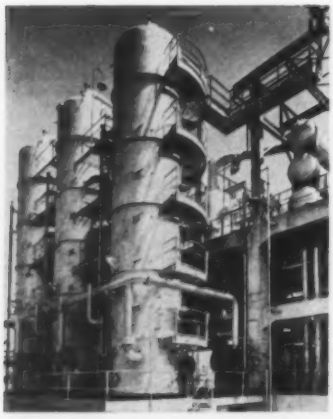
Because of the low degree of unsaturation, butyl stocks are difficult to cure as compared with the diene polymers. It also cannot be used in blends without severe vulcanization problems. Resilience is markedly lower than that of natural rubber. The polymer crystallizes on stretching, and excellent gum tensiles are obtained, approximately 3000 p.s.i. Butyl is similar to natural rubber and neoprene in this respect. The addition of fillers such as carbon blacks will definitely improve many of the physical characteristics such as tear resistance, abrasion, and toughness.

Care must be taken in the choice of plasticizers. Should there be any unsaturation present, as there is in some aliphatic plasticizers, the cure of the compound will be seriously retarded.

Synthetic rubber is put through a tuber machine that squeezes large chunks into smaller pieces and removes water from the rubber. (Photo, U. S. Rubber)

Neoprene rubber

Neoprene is a generic term denoting synthetic rubbers made by emulsion polymerization of 2-chloro-1,3-butadiene, or copolymers containing predominant amounts of this monomer. It is prepared similarly to other emulsion polymers. The polymer is isolated from the latex by a unique process of freeze coagulation on cold rolls, washed, and dried. Several types of crude neoprenes are produced, differing in unvulcanized properties that are important in the processing operations in the manufacture of finished products. Several types of neoprene latex are also available.



Compounding with various ingredients and further processing are carried out as with natural rubber, using regular rubber-processing equipment. Unlike natural rubber and many synthetic rubbers, neoprene is vulcanized with basic oxides (e.g., MgO); sulfur is not necessary in the majority of neoprene compounds. Room-temperature curing compounds have been developed for protection of equipment against abrasion and corrosion.

The tensile strength, elasticity, resilience, and abrasion resistance of neoprene vulcanizates are similar to those of natural rubber stocks. However, its resistance to ozone, sunlight, and chemicals is far better. Exposure to oil causes slight swelling of neoprene stocks, but even in the swollen condition they retain a high proportion of their original characteristics. In applications that require a seal against oil or gas, this slight swelling increases the sealing pressure of the gasket or seal.

Specialty polymers

Polyacrylic ester rubbers: Although the esters of acrylic acids are usually considered as plastics (e.g., polymethyl methacrylate), elastomeric polymers of this type are also available. These polyacrylic rubbers can be cured to give products highly resistant to discoloration, ozone, gas diffusion, and many oils at temperatures up to 350° F. They are not resistant to steam, glycols, or aromatic solvents, nor are they recommended for low-temperature service. Due to their saturated nature, they require special vulcanizing agents, of which polyfunctional amines are the most common. Latices containing elastomeric polymers of acrylate esters are also available and have recently come into considerable use, particularly in protective coatings.

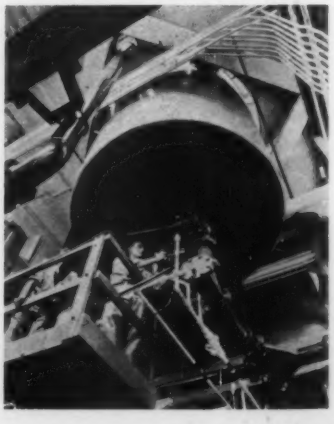
Organic polysulfides: Reactions of organic dihalides and alkali polysulfides yield condensation

Styrene stripping columns. Function of towers is to remove unreacted styrene monomer from latex before coagulation, if final product is to be dry rubber. (Photo, Goodyear)

polymers that vary from viscous liquids to rubberlike products. These polysulfide polymers are also produced in the form of water dispersions.

The polysulfide rubbers are processed and handled like natural rubber. Curing is carried out with metallic oxides (usually zinc oxide). Tensile strength and abrasion resistance are low compared to some of the other synthetic rubbers but are adequate for many purposes. Resistance to aging, ozone, and sunlight are excellent. Permeability to gases is low, and electrical insulation properties are good. The property that makes organic polysulfide rubbers of particular interest is their high solvent resistance. They are serviceable in most aliphatic and aromatic hydrocarbons as well as the common alcohols, ketones, and esters. Protective coatings that give good protection against fresh and salt water, as well as solvent resistance, are based on these polymers. Major uses include hose, printing rollers, permanent putties, gaskets, and binders for various fibrous materials.

Silicone rubbers: Silicone rubbers are a unique group of polymers in which silicon-oxygen linkage has replaced the usual carbon-carbon linkages in the backbone of the polymer chain. The silicone is supplied as a gum which is processed on standard rubber equipment. It is mixed with suitable fillers and cured at high temperatures. Curing is normally carried out by means of peroxidic agents, e.g., benzoyl peroxide. The outstanding properties of the silicones are extreme resistance to temperature changes; they remain flexible over a temperature range of —100 to 500° F. and may be used up to 600° F. in some cases. They are also unaffected by ozone and are highly resistant to hot oils. Electrical properties are excellent. The tensile strength of the polymer is low, and it is attacked by steam, acids, strong alkalies, and some solvents. Very finely divided aluminas and silicas give considerable improvement in tensile strength. Silicone rubbers have found extensive use in wire insulation, tubing, packing, and gaskets, particularly where extreme heat resistance is needed. Dispersions and pastes are also available, and are used for dip coating, spraying, brushing, and spreading.



Polyurethane rubbers: The polyurethane rubbers are elastomeric materials prepared by reacting a polyester or a polyether containing terminal hydroxyl groups with a diisocyanate (e.g., toluene diisocyanate) and so-called "cross-linking" chemicals. Alternatively, the hydroxyl compounds may be treated with a deficiency of diisocyanate to give materials with terminal isocyanate groups which can still be worked, and the final curing carried out with polyfunctional agents such as water, glycols, diamines, and amino-alcohols. When water is used as a cross-linking agent, carbon dioxide is evolved. Therefore, the material must be worked to allow the gas to escape before press curing. The final products from the polymers are characterized by high tensile and tear strengths and excellent abrasion resistance without the necessity for fillers, although reinforcement with carbon black results in still better properties. The first polyurethanes were not resistant to acids or alkalies but some newer types are greatly improved in this respect. In making foams, a polyether or polyester terminated by hydroxyl groups is first reacted with an excess of diisocyanate and thereafter with water and usually a tertiary amine catalyst. Simultaneous polymerization and blowing takes place to form a foam which has high modulus and is useful in making a variety of foam sponge objects.

Fluororubbers: The chemical inertness and insolubility of fluorinated organic compounds is being exploited in the development of polymers for use under extreme conditions of heat and solvent attack. Polytrifluorochloroethylene is already well-established in this field, and other related products are coming into production. Costs are high, but the desired properties outweigh this factor in a wide variety of applications. The fluororubbers are characterized by extreme resistance to solvents and heat, good dielectric strength, and marked lack of adhesive tendencies. Useful temperature ranges extend up to 500° F. for continuous, and to 600° F. for intermittent service.

Chlorosulfonated polyethylene: Another somewhat recent synthetic rubber, Hypalon, is chlorosulfonated polyethylene. It can be compounded with suitable ingredients and the resultant mixes may be used to produce extruded, calendered, or molded products. Also, solutions in solvents may be used for protective coatings.

"Synthetic natural rubber": The new processes devised to synthe-

Discharge lines of polymerization vessel lead to flash tank for removal of unreacted butadiene. (Photo, Goodyear)

size natural rubber are an important progressive step. These rubbers have been checked in all aspects against natural rubber and according to all available reports little or no difference can be found between these synthetic materials and natural rubber. It is known that quite different catalytic systems are used to produce very similar end results. Basically, the reaction is the polymerization of the monomer to cis-1,4-polyisoprene which has a minimum of trans-1,4-polyisoprene. This, in effect, produces a polymer of uniform structure and contributes to the effect of crystallization which in turn aids in obtaining the high gum tensiles and other qualities of natural rubber. Indications are that these new elastomers cannot be produced with the present synthetic rubber type equipment and that new installations as well as procedures will have to be developed before large quantities will be available.

Collapsible fabric containers with synthetic rubber coatings are used in Arctic region to carry fuel for military use. (Photo, U. S. Rubber)

Rubber derivatives

A considerable variety of derivatives, mostly of a resinous nature, are prepared from rubber by treatment with chemical agents. Natural rubber is used primarily as the raw material. Although all of the reactions have been carried out with synthetic rubber (usually butadiene-styrene types), reaction conditions are more drastic, and the products have not reached large-scale production. However, resinous products prepared directly from the monomers used in synthetic rubber production (primarily butadiene-styrene copolymers containing high levels of styrene) have reached very large-scale production and have to a certain extent replaced natural rubber.

Cyclized rubber: Treatment of natural rubber with strongly acidic reagents (sulfuric or sulfonic acids, stannic chloride, etc). causes a rearrangement of the molecules with the formation of cyclic structures. About one-half of the original unsaturation is lost. The resulting products are hard, resinous, and thermoplastic rather than rubbery. They are supplied as powders or granules. They have good solubility and produce flexible films having excellent chemical resistance and low water-vapor penetration. Adhesives based on these products give very strong metal-to-rubber bonds. Major uses are as stiffening agents in natural and synthetic rubber vulcanizates, in paper coatings, as adhesives, in printing inks, and in hot-melt coatings.

Chlorinated rubber: Chlorine both adds and substitutes in the rubber molecule. Products containing 65 to 70% chlorine are produced as thermoplastic resins. They are resistant to the action of moisture, oils, and many corrosive chemicals. Solutions in chlorinated solvents are used for paints and lacquers. Films of low permeability to water can be prepared. Chlorinated rubber is odorless, tasteless, nontoxic, and nonflammable.

Rubber hydrochloride: Hydrogen chloride adds to natural rubber to give a thermoplastic product containing about 30% chlorine. It is produced as film in a variety of thicknesses by solvent-casting techniques. Strength of the film is greatly increased by tensilizing (stretching in two directions). Rubber hydrochloride is used primarily for packaging and in wearing apparel.

Depolymerized rubber: Natural rubber can be depolymerized to such an extent that it is a liquid at normal temperatures. This material is used as a plasticizer for resins, rubber, and the like. It can also be cured by conventional agents and is used as a potting compound, particularly for cable connectors. Liquid synthetic rubbers, particularly polybutadiene and nitrile types, are also available. They are made by direct polymerization to the desired low molecular weight.

Vinyl Polymers and Copolymers

BY B. BAUM*

Although the existence of vinyl resins was known for more than 50 years, it was not until the early 1930's that vinyl polymers and copolymers gained commercial importance. Manufacturers then began to realize that vinyl resins were bringing forth materials which, in their versatility and breadth of application, were unlike anything heretofore developed. Commercial exploitation of vinyls was made possible largely by the incorporation of a plasticizer into the resin formulation. These plasticizers, which are a special class of resin solvents distinguished from ordinary solvents by their low volatility, enable a rigid plastic material to become flexible and therefore useful for many varied applications. In addition, before these versatile vinyl resins could actually be used to advantage commercially, the problem of resin degradation from heat and light had to be resolved. Available today are numerous excellent stabilizers such as salts of cadmium, lead, tin, and barium. These materials protect the resins during processing as well as in their many end applications. The continued development of new resins, plasticizers, stabilizers, and other compounding ingredients offers great future promise for the vinyl industry.

Recent Developments and References were prepared by the editors.

Methods of polymerization

Suspension polymerization: Commercially, the suspension system is the most widely-used method of polymerization; it is applicable to both the polymers and copolymers of vinyl chloride. Suspension polymerization employs a water medium, the water being dispersed in droplet size by a dispersing agent. The catalyst is usually an organic peroxide soluble in the monomer phase. The polymer is filtered from the water suspension in the form of hard, dense particles.

Solution polymerization: In this system, both the monomer and catalyst are dissolved in a suitable solvent. Polymerization takes place in an autoclave at a somewhat elevated temperature. The polymer is usually precipitated from solution, dried, and sold as a finely-divided powder. Due to the poor solubility of polyvinyl chloride, this method is generally used only for copolymers.

Bulk polymerization: In this

RECENT DEVELOPMENTS

Drum liners for hot-melt and tacky materials (Food Film, Inc.), made of polyvinyl alcohol, can handle adhesive and cohesive materials which normally are very difficult to remove from the drum. The liners are preferably placed by air pressure. Molten materials at temperatures up to 400° F. can be poured into them.

Three-dimensional fabrics (*Lum-Puf*, Lumite Div., Chicopee Mills, Inc.), for use in automobile upholstery, seat covers, and outdoor and office furniture, are produced by weaving high-shrinkage saran with normal saran and exposing the fabric to controlled dry heat. The differential shrinkage produces sharply accentuated puffs in the fabric.

A special-purpose viscosity stabilizer (*VS-1*, Camros Chemical Co.) can be used to maintain the original viscosity characteristics of vinyl chloride plastisols over extended periods. Three to 5 parts per hundred parts of resin provide effective stabilization.

A new textile fiber (*Darlan*, B. F. Goodrich Chemical Co.) based on vinylidene dinitrile is extremely soft, resilient, stable, moderately strong, and durable, according to the manufacturer.

A gold ink for printing on vinyl provides good tarnish and greening resistance. (Claremont Pigment Dispersion Corp.)

A vinyl-coated Fortisan awning fabric (*Herculite Awning*, Herculite Protective Fabrics, Inc.), competitively priced with canvas, retains perfect fit under temperature extremes. This fabric is lightweight, durable, and nonflammable. Electronically-welded seams are said to prevent seam failures.

Flexible vinyl film (*Koroseal*, B. F. Goodrich Industrial Products Co.), used as a vapor barrier between roof deck and insulation, prevents drippage of flammable asphalt or tar which can add to the seriousness of industrial fires. The roof vapor-barrier construction (Lexsuco, Inc.) has been proved by Factory Mutual tests as fire retardant with a Class 1 rating.

Cold-reduced steel sheets coated with vinyl (U.S. Steel Co.) promise new decorative effects and long service in such equipment as refrigerators, radio and TV cabinets, wall panels, automotive bodies, stove and heater parts, railroad coach, club, and sleeping car interiors, and office and home furniture.

A clear primer (*69X-1406*, The Stanley Chemical Co.) provides good plastisol adhesion to metal. Effective whether baked or air-dried, it is transparent and colorless and recommended for use

system, the only materials present in the autoclave during polymerization are the monomer and peroxide catalyst. As it forms, the polymer is insoluble in its own monomer; it is then separated in a fluffy form from the monomer by filtering or centrifuging. Bulk, as well as suspension and solution polymerization, gives resins that are free from ionic impurities and therefore useful for electrical applications. Resins polymerized by the bulk method readily absorb plasticizers.

Emulsion polymerization: Vinyl polymers can be polymerized in an aqueous medium containing an emulsifier and a water-soluble initiator. A typical "recipe" would consist of the following ingredients:

Additives	*Parts by weight*
Monomer	100
Water	180
Fatty acid soap (such as sodium lauryl sulfate)	2 to 5
Potassium persulfate	0.1 to 0.5

This technique results in a colloidal suspension of the polymer in water. Emulsion polymerization is more rapid than bulk or solution polymerization, but unlike these methods, it leaves ionic ingredients in the polymer which degrade the electrical properties.

POLYVINYL CHLORIDE

Polyvinyl chloride is a hard, tough, transparent, thermoplastic resin characterized by high inherent strength. One of its outstanding properties is that it can be plasticized to a high degree of flexibility and still maintain appreciable strength. Vinyl chloride resins have exceptional resistance to many chemicals such as acids, alkalies, alcohols, and aliphatic hydrocarbons. In addition, they are resistant to oxidation and are self-extinguishing. These properties are dependent, to a certain extent, upon the modifying ingredients that may be added. Plasticizers, stabilizers, fillers, and pigments may all contribute to a significant change in the properties of the end product. The incorporation of heat stabilizers is required for the commercial use of polyvinyl chloride resins. For outdoor applications, light stabilizers also have to be incorporated. The most important types of polyvinyl chloride resins now being produced are general-purpose, paste-type, and water-dispersed.

General-purpose resins are granular white powders with particle diameters in the range of 0.0025 to 0.0060 inch. They are either round, marble-like spheres, or porous, spongy particles designed to absorb plasticizers faster during processing. The specific gravity of the resin is approximately 1.4, and compound gravities range from 1.24 to 1.7, depending upon type and properties of ingredients. Tensile strength ranges from 1400 p.s.i. in highly plasticized compounds, to 9000 p.s.i. in unplasticized compounds.

Like the general-purpose type, *paste-type resins* are white powders high in molecular weight, but their particle size is much smaller —in the range of 0.1 to 2.0 microns in diameter. These resins are used mainly in plastisol applications. When mixed with a plasticizer and fused by heating, useful end products are formed. The final properties of the compounded

---

under clear plastisol or for other applications where a colored primer would be objectionable. The primer is also available in white, for improved water resistance (*67X-832*), and yellow, for corrosion resistance (*66X-5457*).

A strippable, modified vinyl coating (*I-Sis 88,* I-Sis Chemicals, Inc.), for copper and silver hollowware and flatware, protects them against tarnishing during packaging, shipping, and handling.

Triethyleneglycol dimethacrylate (*SR-205,* Speciality Resins, Inc.) can be used as an alternative for tetra-ethylene glycol dimethacrylate for increasing stiffness and rigidity of plastisols. Among its applications are toys and gaskets.

An anionic dispersed vinyl copolymer latex (*Geon 450X3,* B. F. Goodrich Co.) shows considerable promise for expanding the use of latex paints to include exterior wood and masonry finishes, according to the manufacturer. It is internally plasticized and paint manufacturing is accordingly simplified. The excellent film-forming ability of the vinyl copolymer latex allows paint films to dry rapidly with good strength.

An organosol formulation, 35 parts plasticizer and 100 parts vinyl dispersion resin (*Pliovic AO,* Goodyear Tire and Rubber Co.), is used in decorative and protective coating applications on metal surfaces. The comparatively low plasticizer content permits production of a hard coating with less tack and greater chemical resistance than the more highly plasticized formulations.

A medium-viscosity, general-purpose polyvinyl chloride resin (*Pliovic S70,* Goodyear Tire & Rubber Co.) processes readily at temperatures that would be marginal or impossible for higher molecular weight resins. It can be used as a blending resin for "tempering" high-modulus stocks. The average particle size of this white powder material is 40 microns; the specific gravity, 1.40; and the inherent viscosity, 0.86.

A line of electrical tubings (*Transflex* and *Hyflex,* Irvington Div., Minnesota Mining & Mfg. Co.) has been modified to give fungus resistance without impairing flame resistance or clarity. The tubing is approved for both Class I and Class II (fungus resistance) in both Grade A and Grade B (general and low-temperature) as well as for Categories 1 and 2 (self-extinguishing) for both temperature grades.

A general-purpose polyvinyl chloride electrical insulating compound (*VFD-9033,* Bakelite Co.) is listed as conforming to UL requirements on 75° C. thermoplastic insulated electric blanket wire.

Extruded vinyl waterstop installed in concrete floor effectively resists water pressure. (Photo, Bakelite)

resins are similar to those of the general-purpose compounds, but because more plasticizer is used, in processing, the end products are not so hard.

Water-dispersed resins or latices are finely-divided resin particles, approximately 0.2 micron in diameter, suspended in water to about 50% total solids. The resin gravity is about 1.4, while the latex gravity averages 1.19. It can be modified by adding plasticizers as emulsions, and by using solid modifiers as dispersions.

Polyvinyl chloride resins are blended with various ingredients which make them suitable for many applications. The more important commercial forms are plasticized compounds, dispersions, plastigels, plastic alloys, and vinyl foams.

Plasticized compounds

Plasticizers are added to polyvinyl chloride resins to obtain flexibility. The end use of the compound governs the selection of a particular plasticizer. Through the use of suitable plasticizers, vinyl chloride resins can be formulated for primary electrical insulation and general-purpose wire and cable jacketing material. Such compounds provide high dielectric strength as well as toughness and chemical and moisture resistance. Constituents must be selected for the desired electrical properties. For example, aliphatic plasticizers are preferable for obtaining the best low-temperature flexibility; aromatic esters and polyesters generally impart a low degree of extractability to the end product of the compound.

Recently, there have been several developments of specialized plasticizers for specific applications. One, based on a mixture of iso- and terephthalate, rather than on ortho-phthalate ester, is designed not to mar nitrocellulose lacquer. Another new material satisfies the long-standing demand for a vinyl chloride resin that does not need an external plasticizer. The plasticizer is built into the molecule, therefore eliminating the problems involved in the loss of plasticizer by extraction or volatilization. Also available is a material that acts initially as a plasticizer and can then be polymerized *in situ* with a peroxide catalyst. This new type plasticizer results in the production of a low-viscosity plastisol, but the ultimate product is a hard, rigid material. It also allows a wider latitude in formulation.

Dispersions

There are two commercially useful types of dispersions—plastisols and organosols. Plastisols are mixtures of resins and plasticizers. Organosols contain volatile liquids as well as resin and plasticizers. Thick, tough film can be obtained from these high-solids content materials based on vinyl chloride and vinyl chloride-acetate resins. The dispersion technique has made possible a great number of useful, economical industrial coatings, formed by fusing at approximately 325 to 350° F. These coatings are heavier than those formed with copolymer resin-based solution coatings and are ideally suited for fabric, paper, and wire. The organosols may also be used as high-gloss metal finishes and dip coatings for such applications as electroplating racks and dish drainers. Plastisols can be slush molded into articles of complex shape with thin sections beyond the capability of standard molding equipment.

Plastigels

Through the addition of various metallic soaps or certain organophilic fillers, the plasticizers commonly employed in compounding vinyl chloride resin-based plastisols can be gelled. Such modified plastisols have a putty-like consistency, yet flow readily under moderate pressures. When this pressure is removed, the flow is arrested by the rapid reformation

Vinyl sheets—in both supported and unsupported form—serve as protective coverings and decorator materials in modern interior design. Living room shown below has ceiling canopy and chair upholstery of vinyl sheeting. Wall coverings are textured vinyl and floor is vinyl tile. (Photo, Vinyl Fabrics Institute)

of the gel structure. These gels retain their form up to 400° F. in some instances. Known as plastigels, these substances offer added fields of utility for vinyl chloride resins in dispersion form.

Plastigels may be extruded, calendered, molded, spread, embossed, or otherwise manipulated at room temperatures under moderate pressures such as those used for clay. This gives the plastigels the advantage of being fabricated by ordinary clay or pottery techniques. Floor tile and sheeting can be extruded, embossed, and cured in a strain-free state in the same manner as ceramic tile. Tubing and wire coatings can be extruded under low pressures in the plastigel state and cured in an oven or a hot liquid bath.

Plastic alloys

The use of physical mixtures of polyvinyl chloride and other resins is rapidly expanding. Polyvinyl chloride has been blended with styrene-acrylonitrile, butadiene-acrylonitrile, neoprene, and butadiene-vinylidene chloride to give greater impact resistance to pipe and similar products.

Vinyl foams

Foams are cellular structures formed through the expansion of a fluid material by a gas. The gas is usually evolved by the degradation of a chemical known as a blowing agent which decomposes under heat, giving off copious amounts of gas. The plastic then expands and fills the mold used. If desired, of course, the cavities of the molds can be contoured to specific shapes, e.g., toys, novelties, etc.

Depending on the production technique and formulation, the foams can be open-cell or closed-cell, flexible, or rigid. Among the advantages to be obtained with these materials are good aging properties, chemical resistance, fire resistance, and a low degree of permanent set. An additional feature is the ease with which vinyl foams can be fabricated. Presently employed fabricating techniques include cored and contour molding, molded products with integral surfacing materials, slab or sheet applications, electronically heat-sealed vinyl foam slab, and electronically heat-sealed laminated structures.

Small items being successfully dip molded of vinyl plastisol include tiny tips that cover ends of women's skirt hangers, hand grips for pliers, slip-on covers for keys, and covers for gasoline nozzles. (Photo, B. F. Goodrich)

Applications

One of the initial uses of vinyl chloride resins—electrical insulation—is an extremely large market today. Type TW, vinyl resin wire insulation, combines excellent electrical properties with fire resistance, abrasion resistance, ease of installation, and unlimited durability.

In the form of film (0.003 to 0.010 in.) and sheet (0.010 in. and thicker), vinyl chloride resins have found a practically inexhaustible market. From shower curtains and inflatables to vapor barriers and silo covers, these resins have proved their serviceability. Among the new applications for polyvinyl chloride resins

Vinyl sheeting finds major market outlet in the design of attractive home pools and pool liners. Because of their toughness, the vinyl pools can take a summer's abuse without tearing, peeling, or cracking. Pools are easily disassembled and stored away during the winter. (Photo, Bakelite)

Vinyl coatings are used on river dam because they dry quickly, resist water, and protect against corrosion. (Photo, Bakelite)

are a clear sheeting with excellent transparency for auto seat covers and a highly-polished sheeting for handbags and luggage.

One of the biggest and still-growing uses for vinyl chloride resins is in floor covering. Used most widely in resilient-type tile, these resins offer excellent abrasion resistance and the opportunity for attractive design.

Extruded products include garden hose, refrigerator gaskets, intravenous tubing, window channel seals, sliding door track, cove base for flooring, rigid pipe, and rigid channel strip for window frames.

Some of the more prominent molded plastisol products are soft items such as grommets, slush molded boots, and rotational-cast doll parts. Rigid items, such as molded pipe fittings, phonograph records, electrical plugs, press-formed rigid trays used by photographers, tote boxes, and the like, are molded by conventional methods. High resin content, low-viscosity plastisols have contributed greatly to this expansion in plastisol molding and are expected to contribute even more by making it possible to combine molding and vinyl sponge formation.

Coatings based on polyvinyl chloride resins are applied to cloth, paper, wood, and metal for use as upholstery, clothing, wall paper, and plywood veneer. A growing market for the vinyl coatings is as a protective, attractive, and warm-to-the-touch covering for business machine housings.

POLYVINYL ACETATE

Polyvinyl acetate is prepared by the polymerization of vinyl acetate in the presence of a catalyst in a manner similar to vinyl chloride polymerization. Vinyl acetate resins are characterized by the absence of color, odor, taste, and toxicity. Polyvinyl acetate is available either as a granular resin or as a dispersion in water. These resins are readily soluble in ketones, esters, aromatic hydrocarbons, and chlorinated hydrocarbons. They are insoluble in water, aliphatic hydrocarbons, glycols, higher alcohols, oils, and fats. A large portion of these resins goes into making adhesives and coatings. Properly formulated, they can be applied by brushing, molding, calendering, dipping, and roll coating. Adhesive applications of polyvinyl acetate include the bonding of cellophane, paper, cloth, mica, ceramics, metal, stone, wood, leather, glass, and cellulose ester sheets and film. Commercially, they are used as binders for metallic inks and for textile sizing.

In coating applications, latices of these resins have wide acceptance as a base for sealers, interior wall finishes, and exterior masonry coatings. Polyvinyl acetate latices have excellent pore-filling qualities, are resistant to wood gums, oil-base topcoats, acids, and alkalies, and eliminate the need for flammable solvents. These resins have proved valuable as vehicles for paints and as saturants for fibrous materials where grease resistance and tear and wet strength are among the properties required.

Among recent developments are preparations of vinyl acetate copolymers and terpolymers that give resins of improved water resistance.

POLYVINYL CHLORIDE-ACETATE

Copolymerization of vinyl chloride with vinyl acetate results in a material which retains the toughness and chemical resistance of polyvinyl chloride and has increased flexibility. These copolymers are odorless, tasteless, water-resistant, and self-extinguishing; they possess good dielectric properties and a low order of toxicity. The vinyl chloride content in these copolymers varies from 85 to 97 percent. Both solution and suspension polymerization techniques are being used to manufacture this type of resin.

Also like their parent polymers, vinyl chloride-acetate resins are modified by the addition of plasticizers, heat stabilizers, pigments, and fillers to obtain a variety of products. They are supplied as sheets, rods, tubes, granules, powders, and dispersions, and may be fabricated by standard molding, extrusion, calendering, casting, and coating techniques.

Vinyl chloride-acetate copolymers have been particularly useful as coatings and in the form of unplasticized sheets. These copolymers are ideal for the formulation of solution coatings for a variety of applications. They may be dissolved in ketones, ethers, esters, and chlorinated hydrocarbons. Aromatic hydrocarbons, such as xylene and toluene, are commonly employed as diluents. As sheets, these resins are produced commercially with calendered, matte, or planished finish in a variety of thicknesses, colors, and degrees of transparency. One of the fastest-growing applications for these resins is skin-packaging with cast vinyl film. In this process, film, made by casting dispersions onto a metal belt, is vacuum drawn tightly over the items to be packaged.

Durable, flame- and chemical-resistant fabrics, protective clothing, and filter and anode bags may be woven from extruded vinyl chloride-acetate resin monofilaments, which are shrink-resistant at normal temperatures. Elas-

tomeric materials compounded from this polymer have excellent abrasion resistance, tensile strength, and flexibility over a wide range of temperatures. Elastic sheeting and film of vinyl chloride-acetate resins are used for upholstery, handbags, luggage, gaskets, and packaging applications. Vinyl chloride-acetate resin elastomers may be extruded into rods or tubes for electrical jacketing and insulation.

POLYVINYL ACETALS

These resins differ from polymers of vinyl chloride and vinyl acetate in that they do not result from the polymerization of monomer. Instead, polyvinyl acetals are produced from a condensation of polyvinyl alcohol with an aldehyde. A polyvinyl acetate of a desired molecular weight is first dissolved in a solvent such as methanol and then hydrolyzed to polyvinyl alcohol. This hydrolysis product is reacted with an aldehyde in the presence of moderate heat and a suitable catalyst such as sulfuric or hydrochloric acid to yield a typical cyclic acetal structure. There are three main groups of polyvinyl acetals—polyvinyl acetal itself, made with acetaldehyde, polyvinyl butyral, and polyvinyl formal—all having outstanding adhesive qualities.

Polyvinyl acetal: This resin is used most often in adhesives, impregnating coatings, photographic film, sheets, rods, and tubes. Because vinyl acetal resins have a slight yellowish cast, their usefulness is limited to applications in which color is not a decisive factor. Polyvinyl acetal is processed by casting, coating, extrusion, and molding.

Polyvinyl butyral: Because of its high degree of clarity, even under adverse conditions of moisture, heat, and cold, this resin is best known for its use as an elastic sheeting for safety-glass interlayers. However, it also performs in an outstanding fashion as a base for wash primers or metal conditioners. Applied in an extremely thin film, this conditioner provides an excellent adhesive bond for subsequent coats as well as a temporary resistance to corrosion. Phenolic, alkyd, and oleoresinous paints adhere to the wash primer, usually with improved performance. This primer permits an all-vinyl system to be used in marine and industrial applications. For this application, and for molding compounds, vinyl butyral resins are supplied as solution-grade granules. These resins can also be cross-linked by phenol-formaldehyde and urea-formaldehyde resins to produce coatings and adhesives for bonding rubber, cork, asbestos board, wood, glass, ceramics, cloth, paper, metals, and phenolics.

Polyvinyl formal: Used chiefly in wire coatings in combination with cresylic phenolics, or other impregnants, these resins can also be molded, extruded, or cast. Like polyvinyl butyral, this resin resists alkalies, greases, oils, and water. However, it is not as compatible with other resins as is polyvinyl butyral.

POLYVINYL ALCOHOL

Since vinyl alcohol does not exist in monomeric form, vinyl alcohol resins cannot be prepared by direct polymerization. They are produced by the hydrolysis of polyvinyl acetate in an alcohol solution, using acid or alkali catalysts. Acid catalysis is preferred since it has been found that alkaline hydrolysis gives an undesirable color to the product. The degree of hydrolysis is a governing factor in the properties of the end products. These resins are generally soluble in water.

Polyvinyl alcohol resins are processed by molding, extrusion, and solution coating. These resins produce tough, flexible products that are impervious to gases and water-insoluble solvents, such as aromatic and aliphatic hydrocarbons, chlorinated hydrocarbons, and animal and vegetable oils.

Products made from these resins are used in industrial hose assemblies, lubrication systems, X-ray equipment, and in laboratory and pilot plant installations. In sheet or molded form they are used as diaphragms, gaskets, and friction rollers.

Presently, efforts are underway to improve the water resistance of these materials. Partial acetylation has been one method tried. Another development with this resin is a novel copolymer made with silane monomers for use as a varnish. Other new applications for polyvinyl alcohol are sponges and sizings for glass fibers.

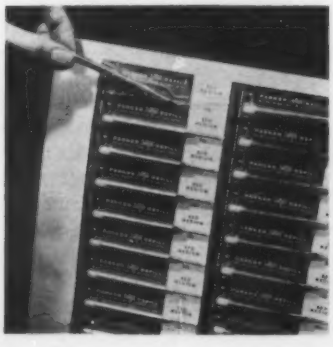
POLYVINYLIDENE CHLORIDE

When vinylidene chloride is polymerized alone or copolymerized with vinyl chloride, a series of resins is produced, ranging from a flexible, moderately soluble material with a softening point of about 160° F., to a hard, tough product with a softening point of 335° F. or more. These resins are characterized by extremely low water vapor-transmission, and exceptional oil, grease, and chemical resistance, These properties are due at least in part to the high crystallinity of the resin.

The basic resins are nonflammable and are soluble only in cyclic ethers and ketones. The insolubility in most chemicals of some vinylidene chloride resins allows them to be used in many applications requiring exceptional chemical resistance. These polymers are compatible with very few other resins and plasticizers; however, they can be modified for specific applications.

Polyvinylidene chloride resins have been found particularly well-suited for injection molding and extrusion. Extruded and oriented, these resins are used in weaving upholstery fabrics, draperies, and weather-resistant screening, as well as for rigid pipe and fittings. In film form, polyvinylidene chloride resins are used for a variety of heat-sealing packaging applications.

Vinylidene chloride has been used most often when copolymerized with vinyl chloride. Because of the greater solubility of this copolymer, these resins are more valuable in the solution coating field than is either homopolymer. Copolymers of vinylidene chloride-vinyl chloride can be used in metal and fabric coatings and in casting or calendering films. These films and coated materials can be easily heat-sealed at



temperatures ranging from 275 to 320° F. The copolymers can also be extruded to produce flexible tubing and electrical insulation for a variety of different applications. Polyvinylidene chloride copolymerized with acrylonitrile also possesses certain advantages for specialized end uses.

OTHER VINYLS

Polyvinyl alkyl ethers: These resins are the result of the homopolymerization and copolymerization of the end-products of the catalytic addition of acetylene to aliphatic alcohols. Polyvinyl methyl ether is a linear polymer characterized by its solubility in an extremely wide variety of solvents, its tacky nature, its solubility in cold but not hot water, and its compatibility with numerous other resins and polymers. It is supplied in unmodified form in 50% aqueous solution, or in 50% solution in various organic solvents such as isopropanol and toluene. Included in this class of resins are vinyl methyl ethers, vinyl ethyl ethers, and a linear copolymer consisting of alternating methyl vinyl ether and maleic anhydride units. This latter resin is soluble in both water and organic solvents. These resins offer good aging characteristics, low order of toxicity, ease of processing, and good adhesive qualities. Applications include pressure-sensitive adhesives, tackifiers in adhesives, and binders in paper, textile, and leather industries.

Considered particularly useful as an ingredient in making pressure-sensitive adhesives are polyvinyl ethyl ethers. For this application, these resins are compounded with varnish-type phenolics or rosin derivatives. In the form of high-molecular-weight resins, polyvinyl ethyl ethers are sold as solvent-free slabs or in heptane solution. Low-molecular-weight polyvinyl ethyl ethers are sold as solvent-free, very viscous liquids and also in heptane solution.

Small items, such as ball-point pen refills, can be economically skin-packaged in cast vinyl film. (Photo, Bakelite)

Polyvinyl pyrrolidone: This resin is prepared by the controlled polymerization of 1-vinyl-2-pyrrolidone to yield products of varying molecular weights. Generally supplied as a white powder that is soluble in water and a great number of organic solvents, the polymer is compatible with many plasticizers, including glycerol, sorbitol, and the ethylene, diethylene, and polyethylene glycols. It is also compatible with polyvinyl alcohol in various ratios.

Because of its inherent inertness and low toxicity, polyvinyl pyrrolidone is extremely important in biological and pharmaceutical applications. It has been found particularly useful as an extender for blood plasma for treatment of shock, certain diseases, and vascular disorders. Other uses of this resin include a gelatinous substitute for photographic emulsions, an agent to increase the solubility of iodine and certain dyes, a stripping agent for textile dyes, a dispersing agent in suspension polymerization, and more recently as an ingredient in hair sprays.

Polyvinyl carbazole: This resin is produced by the polymerization of monomeric *N*-vinyl carbazole, a product of the reaction between carbazole and acetylene. The most outstanding characteristics of these resins are their electrical and chemical resistance. They are resistant to acids and alkalies, and are insoluble in aliphatic hydrocarbons, alcohols, ethers, carbon tetrachloride, and paraffin oils. The impact strength of vinyl carbazole resins is low, but it can be improved by extrusion-orienting the material into fibers at 430° F. These resins are processed by molding, impregnating, or coating.

New vinyl resins: One of the most recently-developed vinyl resins, polyvinyl naphthenate, is particularly useful as a thickener. Copolymerized with vinyl acetate, it promises to be extremely useful as an interlayer for safety glass. Polyvinyl benzoate and polyvinyl fluoride are two other new resins which look promising.

Rigid Vinyls

BY JEAN F. MALONE*

RECENT DEVELOPMENTS

Rigid polyvinyl chloride pipe, valves, and fittings (*Koroseal*, B. F. Goodrich Industrial Products Co.) make it possible to handle active hypo and developer solutions used in film processing like water. In a new motion picture processing laboratory (Consolidated Film Industries), a network of more than 1600 ft. of polyvinyl chloride pipe, 1/10th the cost of special stainless steel pipe and weighing 25% less, carries the solutions through the entire system.

Rigid polyvinyl chloride pipe is to be used by the U.S. Navy for carrying sea water to wash down all exterior parts of a vessel that has been subject to contamination by radioactive fallout. Every ship in the Navy will be thus equipped. Navy specifications are MIL-P-19119 (Bureau of Ships), Nov. 8, 1955, and two amendments, No. 1, April 27, and July 2, 1956.

Polyvinyl chloride lining (*Fligid*, Kaykor Industries, Inc.), for protecting tanks, vessels, and other process equipment against corrosion, is now available in two standard thicknesses, 0.055 in. (*Fligid-55*) and 0.085 in. (*Fligid-85*). The lining, a continuous laminate of plasticized and unplasticized polyvinyl chloride, combines the strength and corrosion resistance of the unplasticized material with the ability of the plasticized PVC to be bonded to other materials.

Vinyl cement (*VC-2*, Schwartz Chemical Co.) is used in bonding rigid polyvinyl chloride pipe for use in such underground installations as sprinkler systems and irrigation projects. The pipe can be joined as soon as it is cemented. In 10 to 15 min., the cement dries.

Unplasticized polyvinyl chloride pipe, duct, and sheeting (*Ryertex Omicron*, Corroplast, Inc.), for chemical- and corrosion-resistant applications, is made from a special low-molecular-weight resin (*Vipla*, Chemore Corp.).

A modified rigid polyvinyl chloride compound (*Vygen 2201*, General Tire Co.) for calendering does not have the rubbery nerve frequently found in rubber-resin blends and has a minimum of heat build-up during processing. A 30-mil sheet can be drawn 9 in. deep.

New equipment (Masland Duraleather Co.) produces rigid vinyl sheets up to 54 in. wide and 102 in. long. Various thicknesses can be achieved, and all materials are laminated and stress relieved.

Rigid polyvinyl chloride materials, also known as unplasticized PVC, were hardly more than a subject of exploratory interest in the United States prior to 1950. Since that time, their unique combination of chemical and physical properties has become well-known. The chemical inertness of rigid vinyls is often their prime recommendation. They can withstand many strong acids and alkalies, metallic and ammonium salts, and organic media such as alcohol and aliphatic hydrocarbons. These excellent chemical properties are combined with equally advantageous physical characteristics. Tensile and flexural strength, abrasion resistance, and heat distortion temperature are among the best of the thermoplastics. In addition, rigid PVC materials will not support combustion, they can be formed on conventional equipment, and their electrical and aging properties are excellent.

* Product Engineer, Plastic Materials, B. F. Goodrich Chemical Co., Cleveland, Ohio.
Recent Developments and References were prepared by the editors.

Classification

At present, there are three distinct types of rigid vinyl. A copolymer of polyvinyl chloride was developed somewhat earlier than the straight PVC types. It has succeeded in capturing a large share of the market in the record industry and is extensively used to make sheet for binder covers, playing cards, relief maps, advertising displays, lighting components, and embossed and patterned wall coverings. The recent development of extruded sheet will probably support a sizable increase in the sale of PVC copolymer to the packaging field and may initiate active competition in the manufacture of refrigerator liners. Projected figures for 1965 indicate that the total volume for rigid vinyl sheet should approach 50 million pounds. Of this volume, the largest portion will be based on PVC copolymers.

The two rigid PVC types are straight, unplasticized polyvinyl chloride. A normal-impact PVC, commonly referred to as Type I, is stronger, more rigid, more resistant to chemicals, and has a higher temperature service range than its companion polymer. Type II is modified during the manufacturing process to obtain increased resistance to impact. The slight loss in chemical and physical properties that results from this modification is not sufficient to interfere with its use except in the most critical applications.

There is a significant difference between the products usually made of the two rigid PVC materials and those made of the rigid copolymer. The latter is predominant in the field of rigid sheet and postformed variations of sheet, while the straight PVC plastics have been successful in heavier structural designs. Both normal- and high-impact stock are extensively used for pipe,

pipe fittings, valves, heavy-gage panels, and many specialized extruded components such as electrical ducts, window and door framing elements, and architectural moldings.

The variations in physical properties among the three rigid vinyl types determine to a large extent their general areas of use. As shown in Table I, below, the values for many properties are mainly equivalent, but distinctive differences do occur in various other properties.

Extrusion of rigid vinyl

Although molding and calendering are important methods of forming normal- and high-impact PVC, extrusion consumes the largest volume and is very likely to increase its lead in the years immediately ahead. A large amount of credit for the growth of extruded products must be given to the improved processing techniques that have been developed. Laboratory and production data have accumulated to the point that reliance on trial and error and personal skill has been largely supplanted by a body of sound technical knowledge. As a direct result, high standards have been established for pipe and tubing, and new markets have been encouraged.

The extrusion of pipe, as an example, has progressed in quality and has become sufficiently standardized to accurately predict performance under specified conditions. Large cross-sections are much less a problem than they once were. A 14-in. pipe, for example, is now being produced as a commercial item. Despite its size, the surface finish is excellent, and roundness and wall thickness are maintained within very small tolerances.

An increasing amount of rigid PVC is being used to extrude custom shapes. In addition to the familiar chemical and outdoor aging characteristics of rigid PVC, many custom applications require strength in thin cross-sections, smooth finish, a wide choice of color, and excellent dimensional stability. These qualities have contributed to the success of window framing and tracks, sliding door channels, trim components for cameras, air conditioning units and refrigerators, architectural moldings, and many other similar designs. Many of the parts listed above bring rigid PVC in direct competition with aluminum and other metals, but increased production rates and lower material costs are closing the margin that originally favored the use of metals.

Improvements have also been made in the design of dies for the extrusion of rigid PVC sheet. Sheet varying from 5 to 120 mils with good uniformity in thickness across the width has been extruded in pilot operations. Dies up to 24 in. in width have already been tested with excellent results. The rate of production is good, and the appearance of the sheet has been generally clear and free of faults. From all reports the development of wider dies will soon prove equally successful. The lower cost of extruded rigid PVC sheet should promote more active participation in competitive areas previously dominated by other plastic materials.

TABLE I: Physical properties of rigid vinyls

	A.S.T.M. Method	*Rigid vinyl copolymer*	*Rigid PVC Type I*	*Rigid PVC Type II*
Specific gravity	792-47T	1.37-1.45	1.38	1.35
Tensile strength, p.s.i.	638-49T	7500	8500	6000
Flexural strength, p.s.i.	790-49T	12,000	13,500	12,000
Flexural modulus, 10^5 p.s.i.	790-49T	4.5-5.0	5.0	3.5
Izod impact, ft.-lb./in. of notch @ 72°F.	256-47T	0.5	0.8	15

Thermal conductivity, 10^{-4} cal./cm.^{2}/sec./°C.		3.7	3.5	4.5

Markets and prospects

The markets for rigid polyvinyl chloride are most commonly divided between pipe, pipe fittings, extruded profiles, and formed sheet applications. Taking this more or less arbitrary division

as a guide, the markets for rigid vinyl products can be outlined as follows:

Pipe: Anticipated volume for 1960 is approximately 50 to 60 million lb., and the growth in use of vinyl pipe is still so active that many predict that this rate of increase will be maintained for a considerable length of time. Foremost applications for rigid vinyl pipe and the reasons that vinyl pipe can be expected to grow in these various fields are listed in Table II, right.

Extruded profiles: Specialized shapes have been expanding very rapidly and can be expected to consume several million pounds by 1960. Gutters, downspouts, framing elements, automotive trim, protective rails, and literally hundreds of other shapes contribute their share.

Sheet: The total of 50 million lb. of rigid vinyl sheet predicted for 1965 consumption will be divided among the classifications listed in Table II, right. There should be a natural expansion in all these applications when the extrusion of sheet becomes commercial, but particular growth may be expected in packaging, laminates, and lighting components. Lower costs should also encourage expansion into new markets such as refrigerator liners, housings, and luggage.

TABLE II: Applications of rigid vinyls

PIPE

Application	*Reasons for use*
Oil fields	Resistant to crude oil and salt water. Very low paraffin build-up.
Gas mains and service lines	Resistant to the impurities carried in natural gas. Not affected by electrolytic corrosion when buried.
Irrigation	Light, easy to install. Can be buried and will maintain full flow for extended periods of time.
General service	Noncontaminating. Easy to install and requires no maintenance.
Chemical industry	Will resist most acids, alkalies, and widely used commercial solvents.
Conduit	Good electrical properties, tough, and resistant to weathering and age. Nonflammable.

SHEET

Application	*Reasons for use*
Packaging	Noncontaminating, clear, easily printed.
Transportation	Durable, waterproof, easily maintained.
Signs and displays	Easily formed. Wide choice of color. Can be silk screened, lithographed, or preprinted.
Lighting and glazing	Good transmission of light, flame-resistant, dull finish for excellent diffusion.
Decorative laminates	Strong, nonflammable, wide choice of color, smooth or embossed finish.
Chemically resistant applications	Inert to most chemicals, easily fabricated, durable, and relatively inexpensive.
Graphic arts	Wide choice of color, fine detail, and easily printed by a variety of methods.
Electrotyping	Takes a fine, clean impression, and is resistant to inks, abrasion, and flexure.
Playing cards	Easily printed in color, easily cleaned, and very durable.
Records	Molds to a very fine detail, improving fidelity and eliminating surface noise. Virtually unbreakable.
Notebook binders	Tough, flexible, variety of color, and easily printed.
Contour maps	Easily and accurately formed; can be colored and printed.

Standards and specifications

The Society of the Plastics Industry has been successful in establishing commercial standards for both rigid sheet and pipe. Late in 1955, the standard for sheet (CS201-55) was published by the U. S. Dept. of Commerce. It governs dimensions and allowable tolerances, uniformity of color, transparency, and finish, and specifies certain chemical and physical requirements. A similar code for pipe (CS207-57) sets specifications for outside diameter, wall thickness, and roundness in cross-section. Standards for hydrostatic burst, impact tests, immersion, flattening, and heat shrinkage are also being considered at the present time. The Bureau of Ships and Army Ordnance, recognizing the increasing importance of rigid vinyls, have developed their own specifications for extrusion and molding compounds, as well as for pipe and sheet.

Vulcanized Fibre

BY J. MACADAM*

One of the oldest plastic materials known to industry, vulcanized fibre is basically a laminate built up from cotton cellulose paper. It differs from other laminates in that the layers of paper are bonded together by the gelatinized surfaces of the cellulose fibers. No added adhesive, resin, or other binder is needed.

The special type of waterleaf paper used for vulcanized fibre manufacture is made in a wide variety of weights, colors, and physical qualities. In the production process the paper is saturated with zinc chloride, which causes the individual cellulose fibers to swell and become covered with a layer of gel. This gelatinized cellulose flows together and so bonds the contacting fibers and layers of paper. Lamination is improved by use of heat, pressure, and time under carefully controlled conditions.

Properties

Based on unit weight (about half that of aluminum), vulcanized fibre is one of the strongest materials available to industry. Depending on grade, tensile strength ranges from 6000 to 12,000 p.s.i.; flexural strength limits are 12,000 to 20,000 p.s.i.; compressive strength is 20,000 to 30,000 p.s.i.; shear strength is 12,000 to 15,000 p.s.i.; and impact strength is 4 to 8 ft.-lb./in. of notch. Rockwell hardness is R60 to R100 and the modulus of elasticity is 750,000 p.s.i. This combination of qualities gives a material capable of absorbing repeated shock and impact loads. Dielectric strength varies with thickness, to values over 300 v./mil. Vulcanized fibre is "Class A" insulation and in heat resistance is superior to cellulose insulation of the unconverted type.

Indicative of the expanding field for this versatile material is the new list of grades defined by N.E.M.A.

Grades

Electrical insulation grade is primarily intended for electrical applications and others involving difficult bending or forming operations. It is sometimes referred to as fishpaper.

Commercial grade is considered the general-purpose grade, sometimes referred to as "Mechanical and electrical grade." It possesses good physical and electrical properties and fabricates well.

Bone grade is characterized by greater hardness and stiffness associated with higher specific gravity. It machines smoother with less tendency to separate the plies in difficult operations.

Trunk and case grade conforms to the mechanical requirements of "Commercial grade," but has better bending qualities and smoother surface.

Flexible grade is made sufficiently soft by incorporating a plasticizer to make it suitable for gaskets, packing, and similar applications. It is not recommended for electrical use.

Abrasive grade is designed as the supporting base for abrasive grit for both disk and drum sanders. It has exceptional tear resistance, ply adhesion, resilience, and toughness.

White tag grade has smooth clean surfaces and can be printed or written on without danger of ink spread.

Bobbin grade is used for the manufacture of textile bobbin beads. It punches well under proper conditions, but is firm enough to resist denting in use. It machines to a very smooth surface.

Railroad grade is for use as railroad track joint, switch rods, and other insulating applications for track circuits. It conforms to A.A.R. Signal Section Specification for Hard Fibre.

Hermetic grade is used as electric motor insulation in hermetically sealed refrigeration units. High purity and low methanol extractables are essential because it is immersed in the refrigerant.

White grade is recommended for applications where whiteness and cleanliness are essential requirements.

Shuttle grade is designed for gluing to wood shuttles to withstand the repeated pounding received in power looms.

Pattern grade is made to have best dimensional stability and least warpage for use as patterns in cutting cloth, leather, and similar materials.

Hamper, trimmed with high-impact styrene, is made of cold embossed vulcanized fibre. Good dimensional stability and chemical resistance dictated choice of material

Resins for Coatings

BY R. A. CALSIBET*

Protective coatings have been used since prehistoric times, but nitrocellulose was one of the first man-made materials used in coatings. First employed in 1855, it was manufactured from wood pulp and nitric acid. Since that time, nitrocellulose has been used in a great variety of industrial lacquers—and is still extensively used today.

Coumarone-indene resins appeared after 1910 and were the first truly synthetic materials available for varnish making. Another very important development at this time was the discovery by Leo H. Baekeland of the first practical phenol-formaldehyde plastic. These new materials marked the beginning of the modern plastics industry. Coating uses, however, were restricted by non-oil solubility.

One of the first applications was the use of baking lacquers for brass beds. This coating was an alcohol solution of a phenolic.

Later, the "Albertols" were developed. These were phenolics modified with natural resins or esters to provide oil-solubility.

The next milestone in the development of synthetic coating resins came in 1928 when a substituted 100% phenolic resin, soluble in drying oils, was developed. This made possible the familiar phenolic varnishes.

After 1928, new coating resins appeared regularly. As each new material took its place, it naturally replaced a number of old material uses, but also developed new markets of its own. Alkyd resins became very important after 1930 and have grown to where they now account for 60% of protective coating resins.

Vinyl coating resins were introduced in the early thirties and acrylate and methacrylate resins for coatings appeared shortly thereafter. Amine resins and chlorinated rubbers also came into the picture about this time.

Styrene resins entered the coatings field about 1937 in the form of a water emulsion, but did not achieve importance until the advent of water-base paints.

The coming of World War II created a tremendous need for all sorts of plastic materials. In the coatings field, in particular, resins came into greatly increased demand for use in the protection of all sorts of critical wartime equipment—as well as to protect against a wide variety of new and difficult conditions that paints had not had to withstand previously. Such was the preoccupation with wartime materiel, however, that the tide of new developments was sharply curtailed.

Probably the most spectacular plastic that grew out of the war was polyethylene. Its use in coating packaging materials such as paper, cellophane, foil, and boxboard has mushroomed over the past decade. Epoxy resins were developed during the war, but were not marketed commercially until later. They have since exhibited an impressive growth pattern in coating metals and other materials. Another extremely fruitful wartime invention was the vinyl butyral wash primer or metal conditioner. First used to protect U. S. Navy ship bottoms, wash primers have now spread to many other applications where metals must be so protected.

Following the war, the development of new techniques and materials was resumed in force, and there have been remarkable strides in the last decade: vinyl dispersions for cloth and metal coatings; vinyl acetate, acrylic, and styrene-butadiene latices for wall paints; styrenated alkyd paints; and petroleum and polyterpene resins for varnishes. A new development in 1954 was the "cold-mix" technique of phenolic varnish preparation which obviated cooking the vehicle.

Cellulose derivatives

Chemistry and manufacture: Cellulose derivatives are prepared by reacting either cotton linters or specially prepared wood pulp with appropriate reagents. All the derivatives can be prepared with varying degrees of substitution and polymerization. Substitution occurs by reaction with the hydroxyl groups of the cellulose molecule. Solubility and compatibility characteristics can be adjusted by varying the type and amount of substitution. Cellulose itself is a very high-molecular weight material, and manufacture of derivatives always involves a reduction in the chain length. As the molecular weight is reduced, solution viscosity, tensile strength, and flexibility are all lowered.

Properties and major applications: Cellulose esters are useful in the preparation of lacquers, and include cellulose nitrate (nitrocellulose), cellulose acetate, cellulose acetate butyrate, and cellulose ethers. Cellulose nitrate is the most widely used derivative for coatings. It is soluble in many solvents, compatible with many resins and plasticizers, and has excellent interior and exterior durability. Almost all cellulose nitrate lacquers are sold for industrial use; the largest markets are auto and furniture finishes.

Cellulose acetate has outstanding clarity and ultra-violet color retention, and has moderate heat- and greaseproofness as well as solvent resistance. It is soluble in only a few high-cost solvents and is not compatible with many other resins and plasticizers. It is used in specialty lacquers where greaseproofness is an asset.

Cellulose acetate butyrate is a mixed ester with wider compatibility with resins and plasticizers than the straight acetate. It is noted for clarity and resistance to discoloration. Cellulose acetate butyrate is used in clear aluminum or aluminum foil coatings, paper coatings, and others.

There are two important celluluose ethers. Ethyl cellulose is used to prepare specialty coatings where alkali resistance, color

Recent Developments and References were prepared by the editors.

Primer coatings are available (National Starch Products Inc.) which provide good adhesion between polyethylene extrusion coatings and such difficult-to-adhere substrates as polyester film (*Mylar*) and foil. These coatings dry tack-free and can be formulated with typical flexographic ink solvents thus giving versatility in the method of application. According to the manufacturer, presence of primer permits lower extrusion temperatures, thereby minimizing possibilities of oxidation and resultant odor formation in the polyethylene.

Half of the latex paint sold in 1960, according to a recent estimate, will be of the polyvinyl acetate type, as compared with about 20% in 1956. In 1948, sales of all latex paints amounted to 2 million gallons; by the end of 1956, they were selling at the rate of 60 million gallons per year.

A free-flowing powder (*Whirlsint K-51*, National Polymer Products, Inc.) specially prepared for use in a coating process (*Whirlclad*) developed by the manufacturer is basically formulated from chlorinated polyethers. Coatings obtained from this material are said to have exceptional chemical resistance, good dimensional stability, excellent mechanical properties, and outstanding electrical characteristics over a wide temperature range.

Two fast-curing surface coating resins (*Cyzac 1006* and *Cyzac 1007*, American Cyanamid Co.) provide maximum hardness and much greater impact and chemical resistance than conventional finishes. Other properties claimed for these "nitrified ester resins" are flexibility, high initial gloss and excellent gloss retention, unusually good enamel stability, and better adhesion than conventional finishes. One of these coating resins (*Cyzac 1006*), generally used with a primer, is intended for applications in which color retention and the hardness-impact relationship are important. The other (*Cyzac 1007*), generally used without a primer, gives baked finishes with unusually good adhesion and impact resistance, and for many applications may be applied over unprimed steel.

A universal spray finish (*Logo R-200*, Logo, Inc.) works well on all polystyrenes and polystyrene copolymers, butyrate, phenolics, polyesters, and other materials.

A colloidal dispersion (*Dispersion No. 235*, Acheson Colloids Co.) of metallic copper in a lacquer solution provides a highly conductive surface coating to nonconductors. It is suggested for printed circuitry, electroplating of nonconductors, and for application on components of radar equipment, hearing aids, and electronic measuring devices. The dispersion is cheaper than other coatings and is applied easier than copper foil.

A brushable coating (*Coverlac SC-242C*, Spraylat Corp.) can be used as a mold release for epoxy resin laminates on plaster molds, as a barrier release coating on metals against epoxy or other adhesive resins during bonding operations, and for masking metal surfaces during spraying and baking cycles. The coating air-dries to form a waterproof, chemical-resistant film that has good heat resistance and is easily peeled from the formed part. The same compound is available in a sprayable consistency (*Coverlac SC-242C-1*).

Two epoxy coating resins (*Maraset gray enamel No. 750* and *Maraset clear varnish No. V760*, Marblette Corp.), characterized by strong adhesion to a variety of materials and excellent resistance to a wide range of chemicals, are useful as an anticorrosion protective coating for chemical equipment.

Sprayable plastisol compounds (*Flintlok* and *Tufkote*, Auburn Button Works) are available in a range of specifications. One group (*Flintloks*) are recommended for coating interiors of storage tanks and processing equipment subject to corrosion, and for application to machinery, to appliances, to equipment, and all metal products. Another group of plastisol sprays (*Tufkotes*) give a thicker, more cushiony coat in textures ranging from shiny or satin to pebble, wrinkle, or leather grain.

A two-component low-density polyurethane coating (*Laminar X-500*, Magna Coatings & Chemical Corp.), catalyzed for air cure, is recommended for protecting magnesium, aluminum alloys, and other metals (ferrous and nonferrous) against corrosion. Available in colors, it can be used on reinforced plastics and wood.

---

stability, low-temperature flexibility, toughness, or good electrical properties are desired. This ether is compatible with waxes, which leads to its use in paper coatings. Other applications include strippable coatings, bowling pin coatings, and cable lacquers. Ethyl hydroxyethyl cellulose is a new entrant in the field. This ether has aliphatic hydrocarbon solubility, and is used widely in silk screen printing inks, where the aliphatic solvents make for better working conditions.

Phenolic resins

Chemistry and manufacture: Phenolic resins are condensation polymers of a phenol and some material that supplies methylene ($-CH_2-$) or substituted methylene linkages, usually formaldehyde. In addition to phenol itself, a number of substituted phenols are commonly used in the production of coating resins. Each of these phenols imparts its own particular group of characteristics to the resin. In general, ortho-

and para-substituted phenols yield oil-dispersible resins, while meta-substituted and pure phenols lead to indispersibility.

The catalyst greatly affects the reaction. Acid catalysts promote rapid resin formation and permanently thermoplastic products. With alkaline catalysts, the reaction proceeds more slowly and oil-insoluble products result unless stopped at an intermediate stage.

Properties and major applications: There are four important types of phenolic resins used in coatings. The *thermoplastic oil-soluble resins* or phenolic varnish resins can be incorporated into a wide variety of coating formulations outstanding in durability, drying speed, water resistance, and toughness. Resistance to many chemicals and solvents is excellent, but strong acids and alkalies should be avoided.

The varnish resins find important uses in spar varnishes; marine and fresh water primers and enamels; structural steel primers and enamels; industrial maintenance finishes; and many others where the maximum weathering protection is required.

The *thermosetting oil-soluble resins* are widely used to upgrade varnishes based on inexpensive natural resins such as rosin and ester gum. The results are markedly improved drying speed, water resistance, chemical and solvent resistance, and durability. These resins greatly accelerate the viscosity-increase rates of oils in the varnish kettle. They are often processed with blown oils to produce air-drying coil impregnating varnishes that are completely through-curing, tough, and solvent-resistant.

The *thermosetting non-oil-soluble resins* are alcohol-soluble baking coatings, and are used where the highest order of chemical and solvent resistance is desired. These materials are used in tank and tank-car linings for milk, wine, and acid. They are also used in many types of chemical processing equipment. In addition, they are compounded into coatings for drums, pails, and other fabricated metal products requiring high chemical and abrasion resistance.

The *phenolic dispersions* are a distinctive class of coating materials. They consist of a dispersion of highly polymerized oil-resin particles in aliphatic or aromatic hydrocarbon liquids. They dry readily, solely by solvent evaporation. In combination with varnishes or alkyds, they form tough, durable, fast-drying, moisture-resistant films having good adhesion to metals. Dispersion finishes are often recoated with lacquer after drying. They are used in corrosion-resistant aircraft primers, quick-drying shop coats, metal product primers, traffic paints, and lacquer undercoats.

Alkyd resins

Chemistry and manufacture: Alkyd resins are normally defined as branched-chain polyesters which have been modified with fatty monobasic acids of the unsaturated type. "Polyester," on the other hand, usually refers only to linear condensation products of glycols and dibasic acids.

The amount and type of oil modification in alkyd resins exerts a profound effect on the final coating properties. Those modified with saturated fatty acids are of the permanently liquid or nondrying type. They are used only as modifiers or plasticizers for nitrocellulose and amine-formaldehyde type resins. Those alkyds modified with unsaturated or "drying"-type fatty acids, harden or "dry" into films, either by air-drying or baking. Alkyds generally contain 30 to 70% oil.

Properties and major applications: Short-oil alkyds contain fewer aliphatic fatty acid chains and hence tend to be incompatible with aliphatic solvents. They are usually supplied as solutions in aromatic solvents. Short-oil alkyds using nonoxidizing oil acids such as coconut or castor are widely used as plasticizers for cellulose nitrate formulations. The alkyd provides adhesion, flexibility, durability, and color retention to automotive and other fast-drying finishes. These alkyds are also baked with urea and melamine resins to give hard, tough coatings for washing machines, refrigerators, home freezers, and other appliances. Such appliance finishes have outstanding gloss and whiteness retention, and resist food stains, detergents, and mild acids and alkalies. Short-oil oxidizing alkyds made with soya or dehydrated castor-oil acids are used in all types of industrial baking finishes. Metal cabinet enamels, automotive enamels, and can coatings are a few of these.

The medium and long-oil alkyds are known widely for their use in many household paints. Using oxidizing oils, these alkyd finishes air-dry to a film of excellent durability and gloss retention. Flat wall paints, enamels, and porch, floor, and deck paints are a few specific examples.

Vinyl resins

Chemistry and manufacture: Vinyl resins are thermoplastic materials made by simple linear polymerization of their monomers. The monomers may be manufactured either from ethylene or acetylene. For example, vinyl chloride may be prepared from the reaction of chlorine on ethylene or hydrogen chloride on ethylene, followed by dehydrochlorination, or hydrogen chloride on acetylene. Likewise, vinyl acetate is obtained from acetylene and acetic acid. The polymerization reactions are usually carried out at moderate temperatures with peroxide catalysts.

Vinyl chloride-acetate and other copolymers are readily prepared from the particular monomers. Polyvinyl alcohol is obtained by hydrolysis of the acetate, and reaction of the alcohol with butyraldehyde yields polyvinyl butyral. Vinylidene chloride monomer is produced by the pyrolysis of trichloroethane or by the treatment of trichloroethane with lime.

Properties and major applications: There are two fundamental ways in which all vinyl resins can be incorporated in coating materials—as solutions or as dispersions. Of the solution coatings, the chloride-acetate copolymers are the most widely used. These resins are applied from ketone solutions to form films of great strength, durability, and abrasion resistance. Chemical resistance is excellent; films are not attacked at normal temperatures by alkalies, mineral acids, alcohols, greases,

oils, or aliphatic hydrocarbons. Permeation by water vapor is extremely low. Higher vinyl chloride content increases chemical and solvent resistance and higher molecular weight increases the abrasion resistance, but these are accomplished with a lowering of solubility, of course.

Baking formulations develop good adhesion to smooth metal. Excellent air-dry adhesion to metal and other difficultly-adhered-to surfaces can be obtained by polymerizing small amounts of other polar groups in the resin. Vinyl copolymer-based coatings are always pigmented for exterior use, and this, coupled with proper additives, provides very good heat and light stabilization. Plasticizers are usually added to increase flexibility or to speed the evaporation of solvents.

One of the chief uses for copolymers has been in linings for beer or soft-drink cans, where they are used as topcoats over phenolic or epoxy primers. Others are marine antifouling paints, masonry coatings, paper milk carton coatings, and maintenance and sanitary enamels.

Polyvinyl butyral forms the basis of the well-known "wash primers." Applied to metal surfaces, wash primers air-dry to provide temporary protection and to serve as a base for the application of topcoats. The most important use of wash primers to date has been in the production of maintenance paints.

Vinyl acetate resins are odorless, tasteless materials with excellent heat-sealability and adhesive properties. They resist weak alkalies, weak acids, and salt solutions. For solution coatings, alcohols and ketones are the usual solvents. Applied from properly formulated solutions, these resins are used for adhesives, in milk cartons, and in paper coatings and leather finishes.

Vinylidene chloride is often copolymerized with acrylonitrile for coating use. The coatings are flexible, strong, and have been found to show outstanding resistance to mineral acids, solvents, and moisture. Applied from ketone solutions, these resins have been used in steel tank linings, pipe linings, maintenance finishes, and in chloride-acetate strippable coatings to provide greater cobwebbing.

In dispersions, the resin, instead of being dissolved in the liquid medium, is suspended in it as very small particles. This overcomes the solubility limitations of vinyls, permitting higher resin solids (60% or more) and the use of the more abrasion- and chemical-resistant grades. Costs are much reduced. Dispersions must be baked after application.

Organosols are vinyl resin dispersions in plasticizer-organic solvent mixtures. They are used as coatings on lawn furniture, office equipment, and on automobile dashboards. Plastisols consist of resin and plasticizer only, and are widely used to coat such consumer items as wire goods and novelties, and many industrial items such as fume ducts, pump impellers, and steel carrying hooks.

A third type of dispersion is polyvinyl acetate latex paint. These coatings dry rapidly by water evaporation to form continuous, tough, non-re-emulsifiable films. They are used widely in interior wall paints, adhesives, and paper and textile finishes.

Acrylates and methacrylates

Chemistry and manufacture: These resins, like the vinyl resins to which they are related, are derivatives of olefinic hydrocarbons. The monomers are prepared by esterifying acrylic or methacrylic acids with alcohols. The monomers may then be polymerized separately, or copolymerized with each other or with other materials such as vinyl chloride.

Properties and major applications: Coating formulations containing these thermoplastic acrylate and methacrylate resins are usually formed from organic solvent solutions or from latices. The methacrylate polymers produce generally harder films with lower flexibility than the acrylate polymers. Also, the methyl esters are generally harder than higher esters such as ethyl or butyl, but are not as flexible. Consequently, methyl methacrylate polymers produce the hardest and most rigid films. Except for the latices, coatings are generally baked and have excellent resistance to water, alcohols, alkalies, acids, oils, and greases. Water-white clarity and excellent light stability permit the use of the full color range, including whites and pastels. Adhesion is enhanced by adding maleic-modified vinyl resins.

Heat-resistant white enamels, fluorescent coatings, cloth coatings, and toilet-seat enamels are a few solution applications. Others are clear coatings for silver, paper, and cloth lampshades, paintings, and raincoats. Decorative and metalized coatings can also be applied to plastic articles.

A newer development is the growing popularity of acrylic latex dispersions for interior and exterior wall paints. These finishes have durability, lack of odor, fast drying speed, and ease of application. They have also been used successfully for coating leather.

Styrene resins

Polystyrene is a polymerization product of vinylbenzene which in turn is derived from ethylene and benzene. Styrene polymerized alone is not too generally used as a coating material because of its brittle nature. Plasticized polystyrene latices, however, have had quite wide use over the last decade in coatings for porous surfaces. Upon drying, these water-base paints form films that have good water and abrasion resistance, acid and alkali resistance, and color retention. Films are nonblocking and have good retention of flexibility on aging and exposure. Polystyrene latices are used in coatings for concrete blocks, wallboard, fresh plaster, paper, leather, and cloth.

Styrene-butadiene copolymers of high styrene content are a very important item in latex paints for interior walls and in clay coatings on paper. As the water content of such coatings dries, the resin particles fuse into tough, elastic films.

Polyethylene resins

Polyethylene resins are essentially long-chain saturated hydrocarbons, and are formed from ethylene by high pressure, temperature, or catalyst. Polyethyl-

ene resins offer an unusual group of properties to the coating field. Abrasion-resistant, flexible, strong, heat-sealable, clear, and light in weight, these resins are practically impervious at ordinary temperatures to mineral acids, strong alkalies, and most nonpolar solvents. Moisture vapor transmission is extremely low.

The most significant coating applications of polyethylene have been in the packaging field, where it has been used in combination with paper, cellophane, foil, boxboard, and others. Hot-solution and hot-melt methods of coating have been used at times for this. The hot-solution technique involves the danger of using hot solvents (at or near their flash point) and hot melting may promote degradation of polyethylene. Thus, in recent years the extrusion coating process has accounted for the lion's share of this market. Extrusion coating is an easy one-step technique that requires no solvents. The resin is hot for short periods only, and the chance of degradation is low.

Of recent commercial significance are white-pigmented polyethylene coatings on boxboard. These materials are being extensively used for packaging bakery products, and undoubtedly will spread to other food products.

Polyethylene-coated paper is being used for multiwall bags; individual packages for food, tobacco, and cosmetics; and photo-sensitive paper. Polyethylene-coated cellophane is excellent for many liquid-containing products such as ketchup, pickles, sauerkraut, suntan oils, and meat. Foil has been made much more suitable and versatile by polyethylene coatings. Cubed beefsteak, instant coffee, dehydrated soup, liquid shampoos, and military protective laminates have used this combination.

Polyethylene resins are being used in increasing quantities to upgrade various different types of paraffin waxes. Milk cartons have been a big market for polyethylene-wax blends. Other uses are for bread wrappers, wax papers, kitchen wraps, and multiwall bags. In short, these blends fit in where an economical coating is desired having properties akin to the unmodified polyethylene materials.

Epoxy resins

Most epoxies used in coatings are condensation polymers of epichlorohydrin and bis-phenol A. By varying the proportion of reactants, a wide range of molecular weights may be obtained. Increasing the amount of epichlorohydrin lowers the molecular weight of the product. The lowest-molecular-weight epoxy resins are viscous liquids, while the highest polymers are hard, brittle solids.

Epoxy resins give outstanding properties to coatings: excellent chemical resistance; excellent flexibility, impact resistance, and abrasion resistance; and superior adhesion to all the commonly coated surfaces. The coatings can be formulated to be resistant to most liquid and gaseous industrial chemicals and products, liquid foodstuffs, and other difficult materials. Only strong mineral acids should be avoided—but fumes and splashes are withstood well.

Epoxy resins may be used in coating formulations three ways. The lower-molecular-weight materials are cured upon application by mixing with reactive materials such as amines or polyamides. The medium - molecular - weight resins are cooked with vegetable-oil acids to form esters, much in the same way as alkyds. Both the amine-cured and esterification-type resins can be formulated for baking or air-drying. The baked resins, naturally, exhibit the better resistance properties, being more fully reacted. In addition, the amine-cured finishes contain a greater proportion of epoxy resin so the epoxy properties are present to a greater degree.

The uses for the amine-cured epoxies are centered where low-temperature conversion, high solids, and high chemical resistance are required. Collapsible tube finishes, electrical insulation varnishes, drum linings, and furniture finishes are important applications. Outside coatings for gas and oil pipelines are an interesting large-volume potential. Tar-epoxy combinations are the latest development in pipes.

Polyamide-cured epoxy resins have been successful on paper and cardboard surfaces, such as boxes, cartons, outdoor signs, and paper book covers.

Markets for epoxy esters include baking coatings for food cans, machine tools, and hardware. Air-dry formulations are used as floor varnishes and as industrial maintenance paints. The highest-molecular-weight resins are used in baking formulations with phenolic, urea, or melamine resins. Having the highest resistance properties of the epoxies, such coatings are found on tank cars and drums, as well as on metal furniture.

Resins for Adhesives

BY R. F. BLOMQUIST*

Development of practical adhesives based on synthetic resins began in this country in the early 1930's with the introduction of urea and phenol resin adhesives for wood and certain other materials. Advances made since that time have been rapid, with much of the stimulation coming from the unusual and often severe requirements for adhesive-bonded components in military uses.

Adhesive bonding

Adhesive bonds offer a number of advantages over mechanical and other methods of fastening:

1) The joining together of certain materials that are difficult or impossible to attach by other methods, e.g., bonding paper labels to cans or bottles.

2) Economical and efficient bonding of small pieces of adherends into larger units, e.g., structural laminated timbers for buildings and naval vessels made up of small pieces of wood bonded together into a large piece.

3) Production of smoother surfaces and contours, e.g., use of adhesives eliminates need for rivets in aerodynamic surfaces in aircraft, and in bonded clutch and brake facings.

4) More efficient and uniform transfer of stresses from one member of the assembly to another, e.g., sandwich panels, prefabricated stressed-cover building panels, adhesive-bonded metal helicopter rotor blades, etc.

5) More efficient design of component parts through better selection of individual components.

6) Less chance of corrosion in joints between dissimilar metals, e.g., adhesive reduces galvanic action caused by direct metal-to-metal contact.

7) Better sealing action for gases and liquids in joints, e.g., assembly of wooden boats with modern water-resistant adhesives.

At the same time, there are certain limitations to adhesive bonding. Authorities are now generally agreed that the actual nature of adhesion is very likely one of specific chemical or physico-chemical attraction of the adhesive for the material bonded. In general, polar adhesives bond best to polar materials, and nonpolar adhesives bond best to nonpolar materials. Thus, to achieve optimum performance, it is necessary to select an adhesive with the proper chemical characteristics.

Joints involving two different adherends are likely to experience particularly significant internal stresses when undergoing changes in temperature or moisture content. Many of these problems of internal stresses may be minimized by modifying the physical properties of the adhesives by judicious incorporation of plasticizers, fillers, etc.

Forms of adhesives

Any adhesive must generally wet the surface to be bonded and must possess a certain amount of flow when bonding pressures are applied, to produce satisfactory bonds. Therefore, most adhesives are used in the liquid form and are generally supplied as liquids, or as solids to be dissolved or dispersed in a solvent at the time of use. Such liquid adhesives may be ready to use as received, or may require the addition of catalysts, fillers, extenders, and other components at the time of use. Tape adhesives are becoming increasingly popular because of their ease of application. These include the pressure-sensitive types that are ready to use, adhesive-coated papers and fabrics to be activated by moistening with water or other solvents, and solid, supported, or unsupported tapes to be cured by hot-pressing.

Types of adhesives

Adhesives may be classified on the basis of the mechanisms by which they harden and develop joint strength, as follows:

Air-drying or solvent-release types: These adhesives are solutions, emulsions, or dispersions of the bonding agent—such as thermoplastic resin or rubber—in water or an organic solvent. In all cases, at least a part of the solvent must be lost from the adhesive film to produce the gelling or hardening by which final bond strength is achieved. The solvent may be lost to the air by open-air drying before the joint is assembled, as with many rubber-base adhesives, or it may be largely transferred into the porous adherends after assembly, as with certain emulsion-type adhesives or water-base adhesives of vegetable gum or starch origin.

Hot-melt or fusible types: Adhesives that can be liquefied sufficiently by melting to produce the necessary flow in bonding are commonly used by the hot-melt process. Such adhesives solidify again upon cooling. Often this is a reversible process, resulting in bonds that are thermally sensitive. Hot-melt adhesives are generally fast-setting and are particularly suitable in such applications as modern high-speed bookbinding and packaging.

Pressure-sensitive types: Such adhesives are characterized by high degrees of initial tackiness so that they bond instantly when slight pressure is momentarily applied to force the two mating surfaces together. Bonds are generally rather low in strength compared to those with other types of adhesives, but their rapid setting under contact pressures makes them extremely attractive, both as liquid adhesives and in the popular pressure-sensitive tapes.

Chemically-reactive types: These adhesives are applied as liquids or as tapes, but are set to an insoluble, infusible state by undergoing a chemical reaction. The rate of this reaction increases

Recent Developments will be found in section on Adhesive Bonding. See p. 818.

as the temperature increases, and may also be controlled by catalysts. Casein glues and certain other adhesives based on natural products may be formulated so that they develop strength and permanence, at least partially, by such chemical reaction. However, most glues of this type are based at present on the various thermosetting resins, and are applied in liquid form. A number of new tape adhesives have recently been introduced, particularly for metal-bonding, which liquefy rapidly when heated in the curing process and subsequently cure by chemical action.

Adhesive materials

Adhesives from materials of natural origin: Many of the earliest adhesives were based on proteins from various natural products. The proteins from hides, sinews, and other animal sources are still widely used as adhesives for wood and paper. They are dispersed in water to form a gel, which is then melted and applied as a hot-melt, or, by protection with suitable gel depressants, cooled again to room temperature for application. Such animal proteins are also used in gummed paper coatings. Casein and soybean proteins are modified with lime and caustic soda to produce important adhesives for wood and paper. Blood proteins are sometimes used alone, but more often with soybean and other proteins, or in combination with thermosetting resins, as plywood adhesives. A practical blood adhesive for room-temperature pressing of interior-type softwood plywood has recently been announced. Carbohydrates such as starches and dextrines are dissolved in water and used primarily as paper adhesives, either in liquid form or as gummed coatings. Other important adhesives based on asphalt are used as mastics in emulsion or solution form to bond flooring tiles to subfloors. Low-cost adhesives based on sulfite paper-mill residues are still used as linoleum cements.

In general, adhesives based on naturally-occurring materials have good dry strength, good permanence under mild conditions, and satisfactory handling properties for many applications. However, they have moderate-to-low resistance to water and high relative humidities. Some improvements in these latter properties can be obtained by incorporation of tanning agents for the proteins or of fungicides to reduce the accompanying biological attack. Such benefits are generally only of limited value for the more severe exposure conditions.

Urea-formaldehyde: These resins enjoy wide popularity, particularly in the wood industries, because of their versatility, light color, and relatively low cost. The basic resins may be formulated with the proper catalysts for pressing either at normal shop temperatures or with added heat. Glue lines may be heated for faster curing by hot platens, heated chambers, or with high frequency. Their widest use is in bonding hardwood plywood for furniture, doors, and other architectural uses. Another important use is in edge-gluing lumber for furniture.

Urea resin adhesive joints are strong when either dry or wet, and have good permanence under mild conditions. However, resistance to continuous or intermittent heat or high humidity will reduce joint strengths significantly. Glue-line costs in plywood made with these adhesives may be reduced by incorporation of wheat flour or other cereal flour extenders, although at some sacrifice in moisture and water resistance. Permanence of the straight urea resin joints may be increased by incorporation of melamine resins or resorcinol. Special formulations are offered for use where thick glues must be tolerated.

Phenol-formaldehyde: These resins are used principally in adhesives for exterior-type softwood plywood, in which bonds (properly made) are more durable than the wood itself, under exterior and other severe service conditions. Thin paper impregnated with a phenol resin is used as a film glue, especially for bonding together very thin, fragile veneers that would be difficult to spread with liquid adhesives.

Phenol resin adhesives are commonly pressed and cured at 270° F. or higher. Attempts to develop practical room-temperature-setting phenol resin adhesives by use of highly acid catalysts have been only moderately successful, because in some cases the strong acids required have damaged wood and other cellulosic fibers being bonded.

Phenol resins are also used for bonding rock wool or glass fibers in roll- or batt-type thermal insulation. They are important components, when modified with thermoplastic resins or synthetic rubbers, in metal-bonding adhesives in aircraft, and for bonding copper or silver foils to insulating plastics laminate backings in the production of printed circuits for electronic equipment. In these applications the adhesive bond must resist the subsequent etching and soldering operations.

Melamine-formaldehyde: Adhesives based on these resins combine the high durability of the phenol resins with the light color of the urea resins. Such adhesives are normally cured at 240° F. or higher. Attempts to reduce the curing temperature of these adhesives have not been promising. At present, melamine resins are used primarily in combinations with urea resins to produce adhesives for hardwood plywood that will meet the standard boil-cycle tests and be suitable for use under the more severe service conditions where straight urea resins are inadequate. Such melamine-urea resins are cured at 240° F. or higher, and tend to approach the high durability of straight melamine resins as the proportion of melamine resin increases.

Resorcinol: Adhesives based on resorcinol resins combine the room-temperature-curing properties of the urea resins with the high permanence of the phenol and melamine resins. They are currently important for laminating wood members for boats and for other exterior uses, such as bridge timbers and utility-pole cross-arms. For gluing strong, high-density species, curing at an elevated temperature may be required. Their relatively high cost has limited their wider use.

New formulations of copoly-

merized phenol-resorcinol resins have reduced the cost of these adhesives somewhat, but further reductions are desirable for wider application, as in prefabricated house panels and laminated barn rafters. Resorcinol resin adhesives are reported to bond well to rubbers and to certain plastics, such as laminates of phenol or melamine resins. Resorcinol resins are also used for coating or priming rayon and nylon tire cords to produce better bonding of the rubber and cords in tire production.

Epoxies: Originally these resins were condensation products of epichlorohydrin with some hydroxy compound, the most typical being bisphenol. The linear polymers produced were then converted into thermoset polymers by cross-linkage with certain reactive groups on the chains by means of carboxylic acid or amine curing agents. Adhesive formulations have thus been developed with either room-temperature-setting properties or the ability to cure at temperatures of 200 to 390° F. Since some resins are liquids and others can be dissolved in reactive solvents, such as allyl glycidyl ether, it is possible to formulate 100% reactive liquid systems for easy application and bonding under contact pressures.

Epoxy resin adhesives will bond remarkably well to a variety of different adherends, including plastics, wood, metals, and glass. These properties recommend their use in the aircraft industry for bonding metal skins to metal or glass-fabric honeycomb cores. Recent requirements for greater degrees of heat resistance for adhesives in aircraft and missiles have stimulated further research on development of new epoxy resins that are based on hydroxy compounds other than bisphenol, on the search for more effective curing agents, and on combinations of epoxy resins with other materials, such as phenol resins.

Vinyls: Vinyl resins, in either solution or emulsion form, have found wide acceptance in bonding applications. Of greatest interest are emulsions of polyvinyl acetate or of copolymers of this resin and other resins. These emulsion adhesives were originally used for bonding paper, for carton sealing, and for similar applications. They have since been reformulated for wood gluing. In the latter use, they are proving suitable particularly for assembly of furniture and cabinet work. Earlier limitations of low moisture and temperature resistance, and of creep and cold flow under sustained stresses have been partially overcome. Recent modifications of polyvinyl resin emulsions with phenol or urea resins have reduced some of these limitations without sacrificing the advantages these emulsion adhesives possess in ease of use and speed of setting.

Cellulosic derivatives: Cellulose esters, particularly cellulose acetate and cellulose nitrate, have long been used in solvent dispersions as household cements. They bond well to paper, and to certain plastics, wood, and leather. They are often used as adhesives in shoe manufacturing.

Acrylates: Polymers of methyl methacrylate and ethyl acrylate are often used as adhesives for plastics, paper, and other materials, where a tough, transparent, flexible film may be required. In some cases the monomer may be used as the adhesive to be polymerized in the joint. Recently, special acrylate resin formulations have been developed for metal-bonding applications.

Polyesters: Esters of maleic and phthalic acids with polyhydroxy compounds (such as glycols) are used as adhesives, or as ingredients in pressure-sensitive adhesive compositions. Unsaturated polyesters, like those of maleic acid and glycols, are used as adhesives for bonding fibrous glass-polyester laminates to themselves.

Isocyanates: Polyurethane derivatives of polyester resins and certain diisocyanates have recently been used to formulate special adhesives for polyurethane elastomers (or foams) and for bonding rubber. These new resins offer interesting bonding properties for several materials.

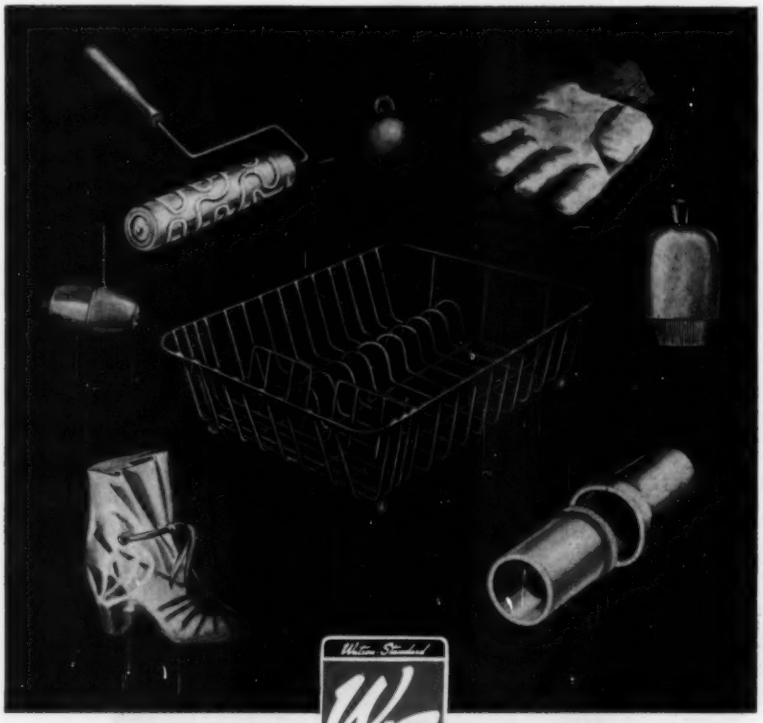
Elastomers: Both natural and synthetic rubbers are widely used as adhesives, mainly as solutions in certain organic solvents. Such adhesives may vary from simple solvent-release adhesives for bonding paper and similar materials at room temperature, where only light bond strength is required, to special thermosetting formulations for heat-curing with special vulcanizing agents. Such rubber-base adhesives are widely used in the fabrication of rubber goods, including tires, for bonding rubber to other materials, such as metals, or for the repair of rubber articles, such as tires and tubes. Recently, neoprene-base cements in organic solvents have been adapted for field application of plastic laminates to plywood (or other bases) for counters and tabletops. These cements are also used in fast, continuous processes for bonding such materials in commercial production, using infrared drying and pinch rollers for applying pressure. This latter process is also being used for industrial bonding of ceramic-coated and other metal surfaces to backings of hardboards or to various of the core materials used in building panels. Similar rubber cements have been adapted for bonding thin wood floor strips and tiles to concrete and other subfloors. Some rubber latices are also used as adhesives.

Combinations of resins

Probably the most important recent developments in adhesives have been those in which two or more basic resin components are combined to produce adhesives with superior properties. Early examples were the casein-rubber latex formulations used for bonding metal facings to plywood. These adhesives are still in use at the present time.

More recently, melamine resins have been added to urea resin adhesives to improve the permanence of the resultant joints. Phenol resins have been combined with resorcinol resin adhesives to reduce the cost without undesirable sacrifices in joint quality or ease of use at lower curing temperatures. Thermoplastic resins, such as polyvinyl acetate or butyral and acrylonitrile-butadiene, or neoprene rubbers, have been combined with phenol res-

ins to produce more adequate structural metal-bonding adhesives. Combinations of phenol and epoxy resins are a recent innovation to produce structural adhesives for use in aircraft where service temperatures above 400° F. are required. One such adhesive in tape form has recently been introduced for use in high-speed jet aircraft. Much additional research is currently in progress to develop better heat-resistant adhesives for such requirements.



Other adhesive components

Solvents: Except for the tape or film adhesives and those applied in molten form, all adhesives must be applied in a liquid form, usually from solution of the components. In most large-scale operations, such as in the paper- and wood-bonding fields, water is the most common solvent. It excels organic solvents in low cost and in freedom from fire and safety hazards. Clean-up of equipment is also much simpler with water-base adhesives. On the other hand, many metal-bonding adhesives are soluble only in organic solvents. The actual solvent composition may be quite complex, particularly for spray application. The solvents (and other diluents and thinners) must be selected with care, not only to produce the desired solution of suitable consistency for application, but also to avoid objectionable changes in viscosity of the adhesive when operating on mechanical roll spreaders during the life of the adhesive, or to avoid any objectionable "cob-webbing" when sprayed. Solvent systems must also be selected to: 1) produce only the desired degree of penetration (or wetting of the surfaces) without any excessive bleeding or strike through, and 2) to result in the desired reactivity of the film at the time the joint is assembled and pressed. With certain resin adhesive systems in solution in rather complex organic solvents, the film surface often "skins over" before adequate loss of solvent occurs. This often results in excessive blisters and blow-ups, particularly with hot-setting formulations, and may require long air-

Watson-Standard

Best known name in

PLASTISOL

Plastisols are versatile. Watson-Standard Laboratories formulate plastisols of special characteristics for a wide variety of end uses. If your product requires a soft plastic coating or molded part you should consider the use of versatile vinyl plastisols. They are adaptable to many methods of application —Spraying, dipping, casting, rotational molding, spread coating, roller-coating, troweling, slush molding.

ACME

DIALLYL PHTHALATE MOLDING COMPOUNDS

superior dielectric materials

- Developed specifically for electrical and electronic components.
- Used as component dielectrics or molded parts in aircraft, automobiles, missiles and communication equipment.
- Combine the prime qualities of high arc-, insulation- and moisture-resistance.
- Resistant to heat, acids, alkali and fungus.
- Superior dimensional stability for many critical mechanical applications where the electrical properties are secondary.
- Available in varied formulas.

There are combinations available in Asbestos, Dacron, Orlon as well as high and medium impact glass-filled material. Many colors available on special order.

Flame retardant molding compounds available and approved by Underwriters Laboratories.

INQUIRIES *are invited for variations on the standard Diallyl Phthalate Molding Compounds. Acme will be happy to work with interested companies on their particular molding requirements.*

drying or precuring at elevated temperatures before actual curing.

Catalysts and curing agents: Modern adhesives based on thermosetting resins develop their strength and permanence by undergoing chemical reactions, the rates of which are dependent on catalysts as well as upon the temperature of the adhesive film. Catalysts may be introduced in the resins or may be added at the time of use. New catalyst systems are continually being developed to provide the best compromises between fast-setting, reasonable pot life, and greatest freedom from undesirable effects on the adhesive or adherend in use. For some years special urea resin systems have been used in certain woodworking operations where fast setting at room temperature is desired and where sufficient catalyst could not be added in the glue mix without excessively reducing the pot life. Here the reactive catalyst is applied to one mating surface and the resin to the other, so that rapid mixing occurs upon assembly and application of pressure. Recently, special automatic metering equipment has been developed to mix epoxy resins and curing agents at the point of application. This equipment permits the use of a very reactive resin system without creating a prohibitively short pot life.

Some resin systems are so reactive that part of the actual reactant must be withheld in the original resin preparation and then added at the time of use. Such components, added in stoichiometric proportions, instead of smaller catalytic amounts, are referred to as curing agents, or hardeners. A good example is the additional formaldehyde added as paraformaldehyde or hexamethylenetetramine to combine with novolak-type phenol and resorcinol resins, or the amine curing agents used to cross-link epoxies.

Fillers and extenders: Materials added to adhesives primarily to improve certain handling properties or performance are referred to as fillers. Walnut or pecan shell flour fillers are commonly incorporated in urea-, resorcinol-, and phenol-resin

woodworking glues to improve consistency for better spreading, and to reduce penetration on the more porous woods. Metals and minerals may be used as fillers in epoxy resin adhesives to improve mechanical properties and to alter the thermal expansion coefficients to approximate more closely those of the metal adherends. Extenders are added primarily to reduce the cost of the adhesive. Examples are wheat and other cereal flour extenders for urea resin plywood adhesives.

FORM: Solid cubes approximately ⅛ inch on a side.

PACKAGING: Polyethylene coated multiwall bags — net weight 50.0 lbs. also, 1500 lbs. and 9000 lbs. U. S. Rubber Sealdbins, for direct shipment from our plant in Tuscola, Ill. Palletized shipments upon request.

COLOR: ALL PETROTHENE types are available in various colors as well as natural.

FREIGHT CLASSIFICATION: By rail — Synthetic Resin, NOIBN
By truck — Plastic Material, Granules
By Express — Synthetic Resins

YOU AND U.S.I.—A PROFITABLE PARTNERSHIP

Here are some of the reasons why you'll find it good business to do business with U.S.I.—

If you mold or extrude polyethylene, you'll find it good business to do business with U.S.I. Here are some of the reasons why: —

A TYPE FOR EVERY NEED — The PETROTHENE compositions now available permit you to make almost any polyethylene item you can sell. "Custom-tailored" compositions can be supplied to meet special requirements.

UNIFORM QUALITY — Precise quality control from natural gas to packaged resin saves processing time: for a given composition, machine settings can remain unchanged through shipment after shipment of resin.

GUARANTEED SUPPLY — Big production facilities located astride a major pipeline insure uninterrupted supply. U.S.I. is the third largest producer of polyethylene today — and is still growing.

FAST DELIVERY — A nationwide sales organization and warehouses in major markets from coast to coast speed delivery of your shipment, whether it be large or small.

TECHNICAL SERVICE — U.S.I. technical service specialists combine thorough knowledge of polyethylene properties with broad experience in processing techniques. They can help you select the right PETROTHENE resin and determine the proper operating conditions for your product and process.

LITERATURE — "Polyethylene Processing Tips", a continuing series of ads in leading plastics magazines, discusses new resin developments and processing techniques. Use the coupon below to make sure you receive each of these informative ads as it appears.

How industry profits from

A Complete Line of Molding Powders . . .

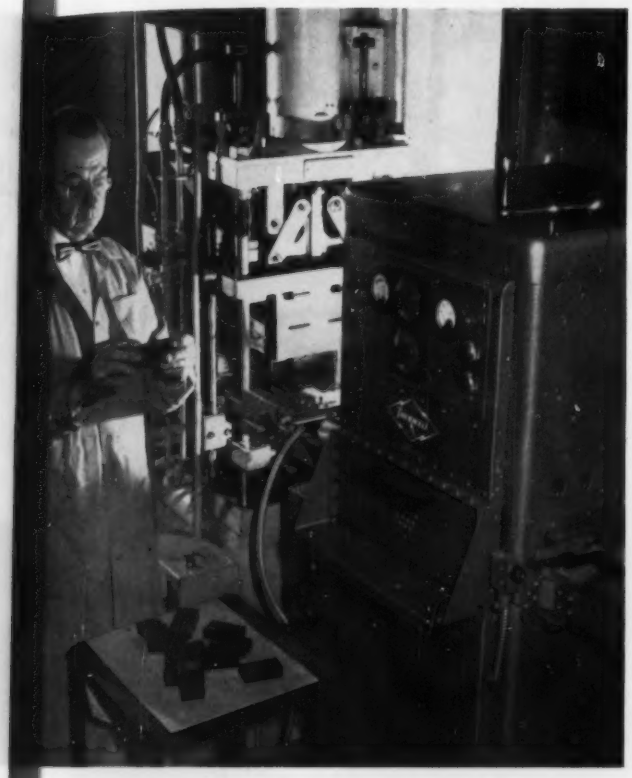
a. GENERAL PURPOSE

Outstanding among general-purpose molding powders are the new G-E 12920 (black) and G-E 12921 (brown). Both offer fast cure, high finish, wide flow range. Mold wear is exceptionally low. Both are suitable for preheated pill and cold powder applications.

b. HEAT RESISTANT

Newest additions to the G-E family of heat resistant molding powders are G-E 12980 and G-E 12981. Both feature low gravity, good dimensional stability, fast preheat and fast cure. With a heat resistance of 500°F and a satin-smooth finish, G-E 12980 is especially recommended for high-performance molded appliance parts. The higher strength and 400°F heat resistance of G-E 12981 are ideally suited to many industrial applications.

c. IMPACT RESISTANT



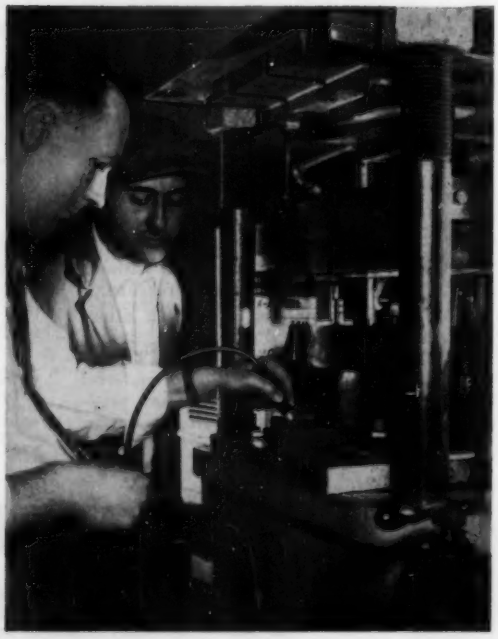
The excellent preform and fast-cure characteristics of the improved impact black G-E 12906 molding powder permit high production cycles and uniform pill weights. Suitable for use on automatic molding machines. Pours fast, preheats fast, takes exceptionally high preheat temperatures without signs of burning. Unsurpassed by any known conventional impact material on the market today.

d. SPECIAL PURPOSE

Indicative of special purpose materials designed to do specific jobs exceptionally well are molding powders for automatic molding, automotive ignition applications and components for electrical apparatus.

G-E progress in phenolics

A Complete Service Program



in the laboratory, G-E research is developing new phenolic molding materials to open up new business opportunities for plastic molders. Here, test parts of improved automatic grade phenolics are being molded for subsequent evaluation.

General Electric's two-stage program is designed to yield a better product and earn a bigger profit for the molder and end-user alike.

Stage One is centered in the G-E laboratories. Here continuous and intensive research develops new phenolic molding materials, new applications, new processing techniques. Thus G-E research helps industry meet today's—and tomorrow's—exacting demands in molded phenolics.

G-E technical service comprises Stage Two. Teams of experts in phenolics are constantly at work in the field and in the laboratory to help the molder and the end-user solve their problems. Their objective is to make your business more profitable by helping you design the part and apply the right molding powder for each job.

Put the G-E program to work in your business—soon. For complete product and service information, write General Electric Company, Section MPE-1, Chemical Materials Department, Pittsfield, Mass.

in the field a G-E technical service specialist helps a molder make initial tests on G-E 12980, new heat-resistant molding powder for appliance parts.

Progress In Phenolics

GENERAL ELECTRIC

From colorful and durable panels for delivery trucks to handsome television cabinets...

Pittsburgh Selectron POLYESTER RESINS

Now Ready For A Thousand New Uses!

Just a few products in which Pittsburgh SELECTRON Resins are now used—

Aircraft structural parts
Radomes for electronic equipment
Life floats
Ballistic panels
Helmets
Boat hulls
Machinery housing and guards
Trays
Tote boxes
Food lockers
Garbage pails
Baskets for automatic dishwashers
Baskets for automatic washers
Wash tubs
Tool chests
Shipping containers
Instrument cases
Laundry hampers
Kitchen containers
Fishing rods
Sinks
Street signs
Traffic signs
Fluorescent light fixtures
Television cabinets
Loudspeaker housings
Gas meter housings
Structural panels for offices and homes
Door and transom lights
Awnings and canopies
Greenhouse panels
Skylighting
Molded chairs
Prefabricated houses and garages
Truck bodies

COUNTLESS products benefit from the combination of beauty and durability Pittsburgh SELECTRON Polyester Resins can give—and usually at reduced manufacturing costs.

SELECTRON Resins are used in products ranging from truck panels that withstand extreme hot and cold, rain, snow, and sleet to television cabinets that serve as focal points of beauty in homes everywhere.

SELECTRON Resins are thermo-setting polyesters which are available in consistency from a thin syrup to extremely high viscosity. They polymerize to form solids, with or without heat and with or without pressure.

When combined with such fillers as fiber glass, cotton, rayon, nylon, felt, sisal, paper, etc., SELECTRON Resins provide a new kind of material that is lighter than aluminum, yet—weight for weight—is stronger than steel. This material has great impact resistance and withstands the deteriorating influence of weather, sunlight, heat, abrasion and many chemicals. It can be molded in durable colors.

Parts in which SELECTRON Resins are used can be molded either by hand lay-up, direct molding, continuous lamination or pre-forming. These resins can also be used without fillers for casting, potting and impregnating.

Investigate the advantages of SELECTRON Resins that may make your products better looking, stronger and more durable. We'll be glad to have one of our engineers discuss your problems with you without cost or obligation. Such a visit may point the way to important production economies and added sales appeal.

Resin Guide

Naugatuck Resin	AVAILABLE FORMS	CHARACTERISTICS OF FINISHED PARTS		
		PHYSICAL	CHEMICAL	ELECTRICAL
KRALASTIC® Resin-Rubber Compounds (Thermoplastic)	Granular, rubber-plasticized resins for: Injection Extrusion	Tough, hard and rigid Dimensionally stable over a wide temperature range High impact resistance Easily machined Can be solvent-welded Light in weight Wide range of opaque colors	Highly resistant to acids, alkalies and other chemicals	Very good dielectric qualities
VIBRIN® Polyester Resins (Thermosetting)	Liquid resins for impregnating glass or other reintorcing fibers for molding by: Pressure or vacuum bag Hand lay-up Molding compounds for matched metal die molding	Strong and tough Good surface hardness Adaptable to very large parts Dimensional stability High heat resistance Unlimited color range; translucent or opaque	Highly resistant to most solvents, acids, bases and salts Low water absorption Good weathering and aging qualities	Good dielectric properties at all commercial frequencies
MARVINOL® Polyvinyl Chloride Resins (Thermoplastic)	White, odorless, tasteless nonhydroscopic powder resins to form compounds for: Molding Extrusion Calendering Dispersion types for: Slush molding Dipping Spraying Coating Rotational molding	May be compounded, plasticized or unplasticized, to give the following properties: Unlimited color possibilities either transparent or opaque Weather resistant Abrasion resistant Strong and tough Non-flammable	Highly resistant to acids, alkalies, alcohol Unplasticized resins are resistant to aliphatic hydrocarbons	Have excellent dielectric properties Can be compounded to meet U.L. requirements

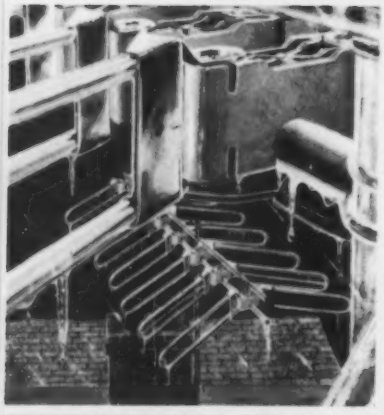
NAUGATUCK Kralastic

RESIN-RUBBER COMPOUNDS

KRALASTIC molding and extruding compounds are unique combinations of thermoplastic resins and nitrile rubber. The result is an almost indestructible end product of exceptional strength, toughness and impact resistance.

Extruded as plastic pipe, Kralastic has proved phenominally successful and durable in transporting salt water and sour crude in the oil fields; carrying natural gas, drinking water, corrosive chemicals, irrigating [illegible] and as money-saving, quickly-installed electrical conduit.

The new Kralastic HTHT (high temperature, high tensile) compound now extends the usefulness of thermoplastic pipe.



Other Kralastic compounds are under development to meet special needs and may be ready for commercial use by the time you read this. We suggest you consult us regarding your specific requirements. Also write for a reprint of a recent article giving the results of independently conducted weathering tests in which Kralastic pipe proved its superiority over other plastic pipes.

More than 6,000 miles of Kralastic pipe for all purposes were in service by mid-1957. Kralastic pipe now has NSF approval for drinking water service.

All wheels and part of the housing of this mower are Kralastic. The drive wheels have internal gear teeth molded into them.

This TV antenna takes advantage of Kralastic's excellent electrical, physical and weathering properties in its molded Kralastic brackets.

More than 25 million hair combs have been made of Kralastic. One manufacturer guarantees every Kralastic comb against tooth breakage for one year.

Distinctive Properties:

- High impact resistance
- Extreme toughness and hardness
- Light weight: 1/2 weight of aluminum; 1/7 weight of iron
- Non-corrosive, non-electrolytic
- Readily sawed, drilled, threaded
- Quickly solvent-welded
- Dimensionally stable over a wide temperature range
- Opaque built-in colors

Major Uses:

- Pipe and pipe fittings
- Light wheels, gears and pulleys
- Durable hair combs
- Machine housings and parts
- Textile warp tubes and bobbins
- Radio and camera cases
- Football and safety helmets
- Tote boxes
- Hose nozzles and fertilizer injectors

NAUGATUCK Vibrin

LIQUID POLYESTER RESINS

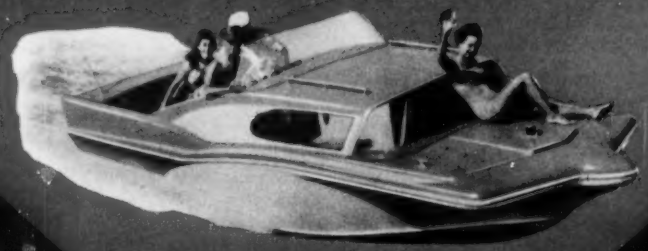
With the aid of a catalyst, these unsaturated liquid polyester resins are rapidly converted to solids with little or no heat or pressure other than the exothermic heat created by their chemical reaction. Being 100% reactive, they evolve no gas or liquid during cure.

Vibrin resins are used primarily with glass or other fibers in the form of cloth or mat to produce thermo-setting reinforced plastic products which are extremely strong and impact-resistant.

Naugatuck is prominent as a supplier of polyester resins for hand lay-up molding of large parts. In the booming boat-building field, Naugatuck is the leading resin supplier.

In addition to a wide range of resins for every type of molding, Naugatuck also offers Vibrin VPA parting agent for easy mold release, and several types of shell coatings to give a smooth, non-porous pigmented outer surface to Vibrin moldings.

Distinctive Properties:



Vibrin, reinforced with glass fibers, has these properties:

- **Stronger per pound than steel**
- **Economical for large prototype production in small or moderate quantities**
- **Non-denting; impact-resistant**
- **Chemical- and weather-resistant**
- **Can be pigmented or painted over**

Major Uses:

- **Boat hulls and deck units**
- **Auto and truck bodies**
- **Sectional swimming pools**
- **Translucent windows and skylights**
- **Chemically inert pipe**
- **Furniture**
- **Corrugated paneling**
- **Machine housings**
- **Fishing rods**
- **Cements and putties**

	VIBRIN 135 High Heat Resistant	VIBRIN 144D Self-Extinguishing	VIBRIN 151 Resilient
DESCRIPTION	Clear liquid triallyl cyanurate polyester resin	Straw-colored, liquid polyester resin Flame-resistant	Clear, liquid polyester resin providing high resilience
SPECIAL FEATURES	High strength retention at 500° F Short term exposure at 600° F	Fire retardant and self-extinguishing	Elongates 5% Has outstanding toughness and impact strength
RECOMMENDED USES	Aircraft, missiles, jets, radomes, heat-resistant parts High temp. electrical parts	For production of products which must not support combustion	Impact-resistant products. Pressure bag, vacuum bag or hand lay-up molding and putties

Radical hull contouring is neither difficult nor very costly when molded of glass-fiber reinforced Vibrin—the boating industry's most widely used polyester.

Glass fibers imbedded in brightly pigmented Vibrin give distinctive textural beauty to this decorator bowl.

Weight-saving reinforced Vibrin is easily fabricated into curved components and allows area reinforcement in sections subject to heavy road shock or impact damage.

Cold frames and green houses of reinforced Vibrin have all the sunlight translucency and transmission of beneficial ultra-violet light needed—yet protect against extremes of weather.

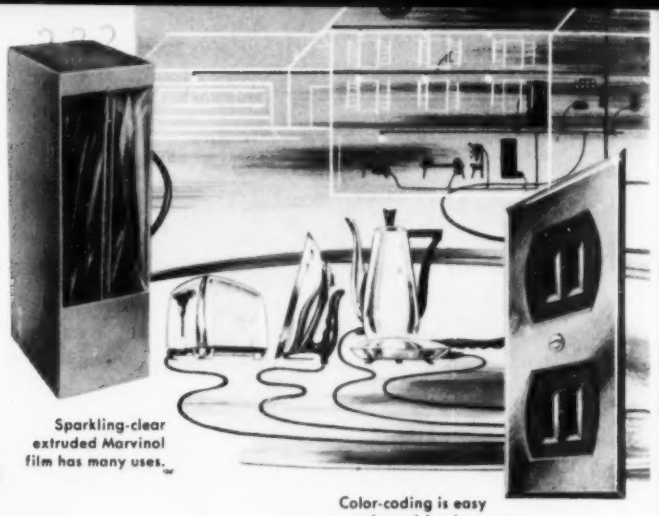
VIBRIN 152-LS-4 Light-Stabilized	VIBRIN 154 Room Temperature Curing	VIBRIN 156 Reactive, Fast Curing Polyester Resin	VIBRIN X1068B Minimum Shrinkage Potting
Higher viscosity liquid polyester resin stabilized to prevent discoloration	Pre-accelerated, thixotropic, polyester laminating resin	Clear, light liquid	Clear amber, accelerated polyester resin
Shows negligible change in color from sunlight and weather exposure	Ready to use after catalyst addition Non-sagging, fast-curing	High hot strength, toughness, rapid cure	Ready to use after catalyst addition. Minimum exotherm and shrinkage
Flat or corrugated panels for colorful outdoor and architectural purposes	Hand lay-up, room temp. curing applications such as boats, pools and tanks	Matched die molding premix compounds. Button molding and casting. Modifications of Vibrin 156 are available for each of above uses	Potting, encapsulating, cements, where minimum stress build-up is important

NAUGATUCK Marvinol

POLYVINYL CHLORIDE RESINS

Polyvinyl chloride resins and their host of varied uses are well known to the industry. As a major supplier of vinyl resins, Naugatuck is constantly developing additional Marvinol resins, of high, medium and low molecular weights, with specific processing and end-product qualities.

The 12 Marvinol resins listed below constitute what is probably the most extensive line of straight PVC resins available for calendering, etc., from any one manufacturer. Of these, VR-22 and VR-23 electrical grade extrusion resins have Underwriters' Laboratories Inc. approval. Marvinol VR-24 is used in semi-rigid insulation for low-voltage communications wiring insulation where UL approval is not required.



Particularly outstanding in the Marvinol line are the new resins VR-50 and VR-51 recommended for plastisol and organosol applications, since Naugatuck has taken the lead in developing outstanding rheological characteristics in these resins.

	MARVINOL VR-10	MARVINOL VR-12	MARVINOL VR-20	MARVINOL VR-22
Description	Modifying resin for plastisol compounding.	Specialty calendering and extrusion resin.	Specialty film calendering resin.	Electrical grade, hot, dry blend resin for extrusion.
Special Features	High molecular weight resin for modifying plastisol formulations. Imparts dryness of hand (dullness), maintains high physical properties, produces lower Brookfield viscosities, promotes good air release in slush and rotational molding plastisol compounds. Used in blown film formulations for high physicals and speeds.	High molecular weight straight PVC resin for imparting special qualities of dry hand (dullness) coupled with excellent physical properties. Demonstrates fast milling and Banbury mix characteristics together with high premix densities in plasticized formulations. Has outstanding high-speed extrusion properties permitting close dimensional tolerances.	Medium molecular weight. Recommended primarily for calendered film where unusually good light stability and clarity are required. Excellent hot or cold premixing. Has high bulk density for large Banbury charges.	Medium-high molecular weight with high bulk density for large Banbury charges. Excellent mixing cycles for hot, dry blend extrusion. Possesses excellent electrical properties and is approved by Underwriters' Laboratories, Inc. for electrical applications. Inherent heat stability.
Resin Properties

Dolls look and feel lifelike when made of Marvinol

Sparkling-clear extruded Marvinol film has many uses.

Color-coding is easy when wiring is Marvinol-insulated.

Distinctive Properties

Marvinol vinyls may be compounded to yield products having these properties:

- Extreme versatility—from transparent film to opaque rigidity and hardness
- Light weight
- Strength and toughness
- Inert to most chemicals
- Excellent electrical properties
- Resistance to weathering and abrasion
- Flame resistance

MARVINOL VR-23	MARVINOL VR-24	MARVINOL VR-25	MARVINOL VR-31	MARVINOL VR-33	MARVINOL VR-34
Electrical grade, easy processing, hot, dry blend resin for extrusion and calendering.	Easy processing, calendering and extrusion resin.	Low molecular weight processing-aid resin.	Cold, dry premix resin for calendered film, sheeting and coated fabrics.	Cold, dry premix resin for calendered film sheeting and coated fabrics.	Easy processing, cold, dry premix resin for calendered film, sheeting and coated fabrics.
Medium molecular weight with high bulk density for large Banbury loadings. Fast extrusion rates at low power consumption from dry blends or compounds. Superior electrical properties approved by Underwriters' Laboratories, Inc. for electrical applications with excellent heat stability.	Medium-low molecular weight straight PVC. Very high bulk density, valuable processing characteristics in semi-rigid calender formulations. With higher molecular weight resins acts as a processing aid. Useful in rigid and semi-rigid wire extrusion compounds.	Low molecular weight straight PVC resin ideally suited for: A. An additive in vinyl-asbestos flooring formulations and in high-fidelity phonograph record compounds. B. Injection molding of unmodified rigid PVC applications.	Medium-high molecular weight. Gives cold, dry premixes. Leaves mixers clean and minimizes clean-out problems. Excellent for the calendering of film sheeting and coated fabrics.	Medium molecular weight, cold, dry pre-mixing resin. Leaves mixers clean and minimizes clean-out problems. Excellent for calendered inflatable film, for sheeting and for coated fabrics. Excellent heat-sealing properties. Produces outstanding injection-molding compounds.	Medium-low molecular weight, cold, dry premixing resin. Minimizes mixer clean-outs. Mills and Banburys rapidly. Used for calendering film for inflatables, sheeting and coated fabrics where an outstanding easier-processing resin is required.

NAUGATUCK Marvibond*

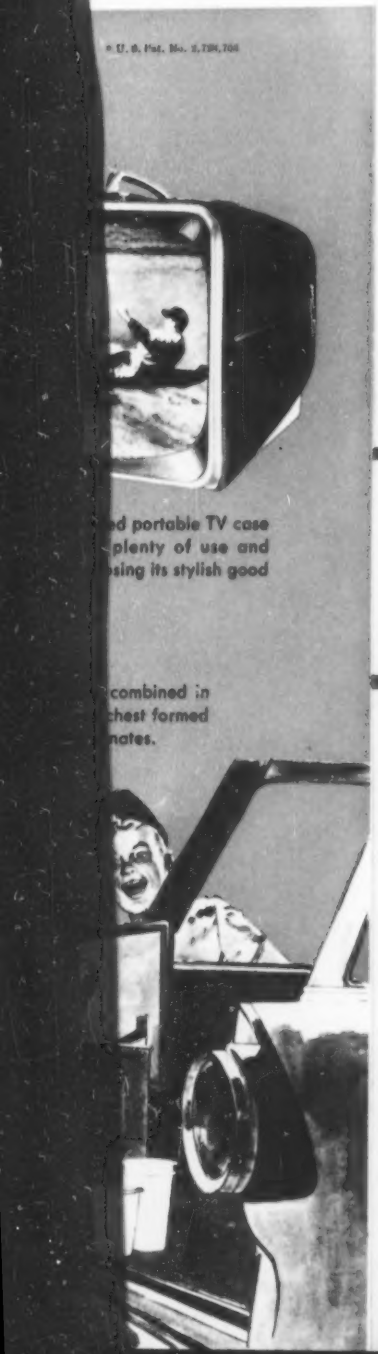
VINYL-TO-METAL LAMINATING PROCESS

The Marvibond process, developed and patented by Naugatuck, is a technique for laminating a specially formulated semi-rigid Marvinol vinyl film or sheeting to almost any kind of sheet metal on a continuous basis. The vinyl provides a permanent, durable and rich-looking finish while the metal supplies structural strength.

Marvibond laminates can be embossed, sheared, drawn, drilled or crimped using standard metalworking equipment. The items shown below only begin to suggest the product possibilities. Marvibond laminates are available from a number of laminators. Write us for the current list of Marvibond licensees.

* U. S. Pat. No. 2,739,706

Sweating glasses and spilled drinks will never mar the smart beauty of this hostess cart's Marvibonded vinyl surfaces.



This Marvibonded portable TV case will withstand plenty of use and abuse without losing its stylish good looks.

Beauty and utility are combined in this picnic jug and ice chest formed from Marvibonded laminates.

You've got a molding problem! You want a polystyrene that's more durable, more lustrous, more dependable in its yield of perfect pieces.

Have you looked into Fostarene?

Fostarene is a product of a pioneer in plastics for over 30 years. In talent and equipment, Fostarene's research facilities are second to none . . . *and growing!*

The result: Better performance, better service for more and more molders who have made the discovery *you* can make—that when it comes to polystyrene, the smart move is to investigate Fostarene.

EXON RESINS

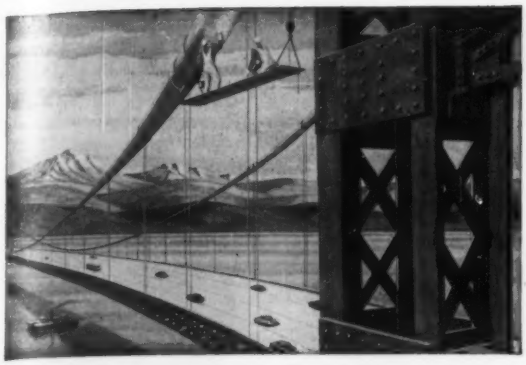
GIVE YOU SHORT CUTS TO FINER PRODUCTS

Here are just 9 of the many different ways industry's most complete line of specifically engineered vinyl resins answer specific production needs.

EXON 402-A—Top corrosion-fighter in industry. Can be processed into a variety of useful forms such as sheets and rods. Can be cemented or welded. Lightweight, easy to work.

EXON 450—Ideal for strip coatings. Good solubility, film tensile strength and durability.

EXON 468—Engineered for flooring. High bulking density increases banbury output 10 to 25%. Fast fusing at low temperatures for much easier, more efficient processing.



EXON 470—Exhibits excellent adhesion to metals, alkyd and vinyl surfaces. Compatible with a wide range of drying oils, alkyds, phenolics, melamines. High solubility in inexpensive solvents.

PLUS . . . **EXON 461**—a unique fluorine-containing resin combining high solubility, unusual chemical resistance, heat stability and weatherability.

EXON 500—specifically engineered for wire insulation with superior electrical properties.

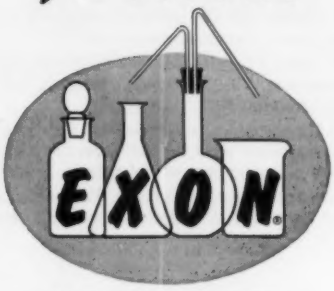
EXON 700 XR 59—an exceptionally fast-fusing latex for impregnation.

EXON 485—For superior strip coatings. Lower viscosity makes application easier and shelf-lift better. Good clarity.

EXON 471—Excellent weatherability and durability in a protective coating. Corrosion resistant. No measurable change after sunlamp exposure for 360 hours as 1 mil film.

EXON 480—For phonograph records. High bulking density and easy processing at low temperatures. Completely compatible with extender resins, stabilizers and pigments.

EXON 481—Makes possible colorful, abrasion-proof, washable coatings that resist fading or cracking.



EXON 654—The versatile plastisol resin. Basis of vinyl foam tailored to your needs. A top performer for slush molding, rotational casting, fabric coating. Needs no grinding.

EXON 905-915-925—Temperature tailored, they free your processing from restrictions due to temperature limitations. Blend speedily, fuse quickly.

The versatility of Exon vinyl resins has been demonstrated in far more applications than we have space to describe. The uses mentioned only *typify* the economy, efficiency, and ease of processing for which these resins are engineered.

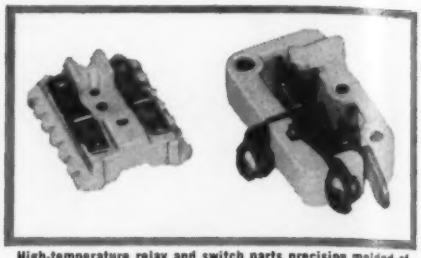
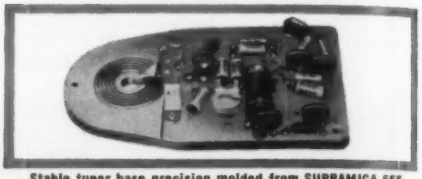
DESIGN ACHIEVEMENTS WITH SUPRAMICA* ceramoplastics

SUPRAMICA ceramoplastics . . . . . .



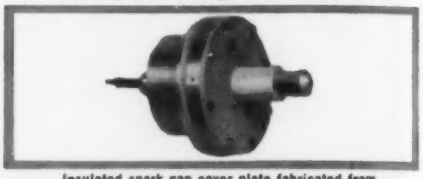
MOLDED OR MACHINABLE HIGH TEMPERATURE INSULATION

Supramica ceramoplastics, the world's most nearly perfect high temperature insulations, are formulated with SYNTHAMICA* synthetic mica. Supramica possesses high temperature and thermal shock resistance, and complete dimensional stability. Thermal expansion coefficients are the same as steel. They have low electrical loss, excellent arc resistance, high dielectric strength, and are impervious to moisture, oil and organic solvents, with permanent resistance to radiation.



SUPRAMICA* 560 — New insulation for **continuous operation** at 500° C (932° F). Lightweight material can be precision molded with fragile inserts . . . specified for conditions **which no other material can meet!** Specific gravity similar to that of aluminum or mineral-filled polyesters . . . perfect for relay bases, connectors, radomes, tube sockets and other components for high temperature use.

SUPRAMICA* 555 — Precision-molded ceramoplastic having high-temperature endurance up to 750° F. Moldable with or without inserts.



SUPRAMICA* 500 — Compression-molded ceramoplastic sheets and rods for use at temperatures up to 900° F. Readily machinable; not precision moldable. Inserts must be cemented.

High-temperature relay and switch parts precision molded of SUPRAMICA 560 ceramoplastic

Stable tuner base precision molded from SUPRAMICA 555 ceramoplastic with fragile silver ribbon insert

Insulated spark gap cover plate fabricated from SUPRAMICA 500 ceramoplastic

MYCALEX* glass-bonded mica . . .

MOLDED OR MACHINABLE ELECTRICAL INSULATION

Mycalex glass-bonded mica formulations have been recognized for many years as high-temperature, high-frequency insulation . . . impervious to oil and water, resistant to high temperatures, with total, permanent dimensional stability and thermal expansion coefficient equivalent to that of insert metals . . . resistant to radiation.

MYCALEX 410* Glass-bonded mica precision-molded with or without inserts, for applications involving temperatures up to 650° F.

MYCALEX 400* Standard compression molded glass-bonded mica for operating temperatures to 850° F. Readily machinable, but not moldable. Inserts must be cemented.

MYCALEX* 385 Glass-bonded mica with excellent resistance to circuit breaker arcing and thermal shock, for continuous operating temperatures up to 700° F. Readily machinable, but not moldable in intricate shapes.

MYCALEX* K (machinable) and KM (moldable) Glass-bonded mica capacitor dielectrics with higher dielectric constant indicated by numbers 10, 20, 30.

High shock potentiometer parts precision molded with steel supporting inserts — MYCALEX 410 glass-bonded mica

Radar insulating parts fabricated from MYCALEX 400 glass-bonded mica

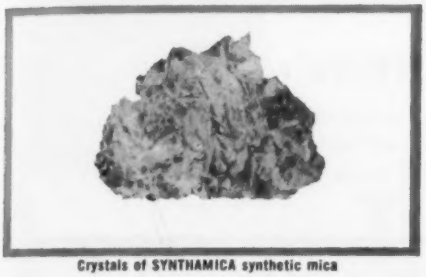
Circuit breaker arc chute fabricated from MYCALEX 385 glass-bonded mica

* "SUPRAMICA", "MYCALEX", "400", "410", are registered trade-marks of MYCALEX CORPORATION OF AMERICA; "500", "555", "560" and "385" are trade-marks of MYCALEX CORPORATION OF AMERICA

"SYNTHAMICA" is a trade-mark of SYNTHETIC MICA CORPORATION, a subsidiary of MYCALEX CORPORATION OF AMERICA.

AND MYCALEX* glass-bonded mica . . . . . .

MYCALEX TM Commutation Switch with commutator plates precision molded of SUPRAMICA 555 ceramoplastic. Plate is CP-346, 2-poles, 360 contacts.



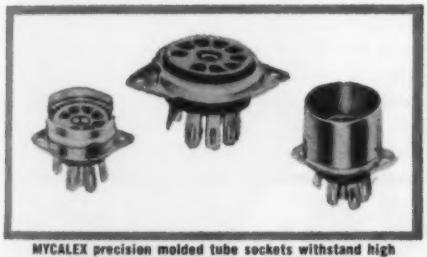
MYCALEX TM telemetering switches

WITH SUPRAMICA CERAMOPLASTIC COMMUTATOR PLATES ASSURE RELIABLE OPERATION UNDER EXTREME CONDITIONS

Precision-molded Supramica ceramoplastic commutator plates have introduced a degree of accuracy and sustained dependability never before approached in telemetry. Where warpage of only .0002" of the commutator plate will distort and destroy the value of the signal, these precision switches withstand extremes of temperature, altitude, shock and vibration and deliver a clean, unvarying signal . . . tests show completely satisfactory performance of these switches after more than 1000 hours at 1200 RPM.

In military and industrial applications, Mycalex TM Telemetering Switches with Supramica ceramoplastic commutator plates have made significant contributions to the reliability of electronic equipment.

MYCALEX ELECTRONICS CORPORATION



Crystals of SYNTHAMICA synthetic mica

SYNTHAMICA* synthetic mica . . . .

Available in commercial quantities, as powder, flake or crystal, and in chemically bonded sheets for all applications in the electronic, communications and related industries. Manufactured from readily available native raw materials, Synthamica synthetic mica is an important contribution to the development of military and civilian electronics.

Synthamica synthetic mica is chemically pure, hydroxyl free, and will withstand temperatures almost twice as high as its natural counterpart. One of the outstanding properties of this crystal clear material is the freedom from outgassing at elevated temperatures and pressures.

SYNTHETIC MICA CORPORATION
A Subsidiary of MYCALEX CORPORATION OF AMERICA

MYCALEX precision molded tube sockets withstand high temperatures and rugged service. Standard miniature and subminiature types.

MYCALEX tube sockets . . . . . .

High temperature tube sockets made from Supramica ceramoplastic and Mycalex glass-bonded mica are produced under exclusive license of Mycalex Corporation of America.

Supramica 560 ceramoplastic tube sockets have successfully passed operating tests at 500° C.

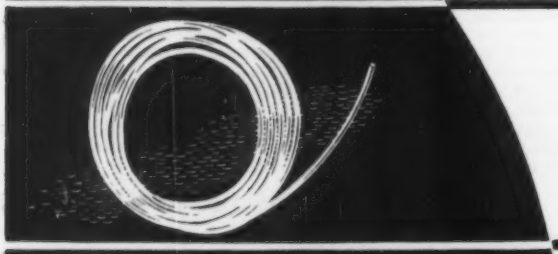
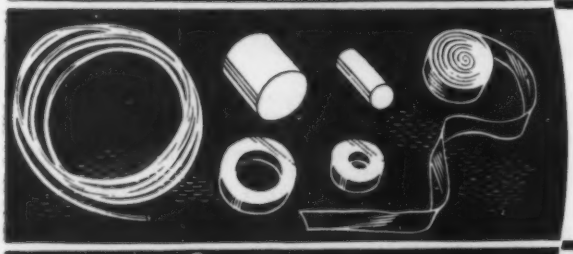
Select **POLYPENCO®** Industrial Plastics



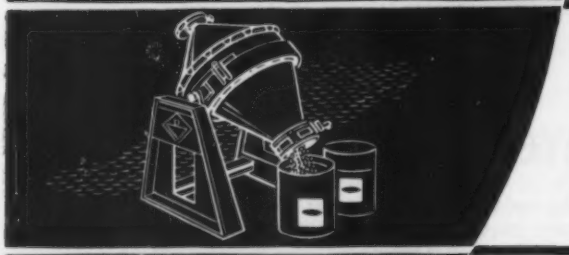
Polypenco products and engineering service are your answer to new developments, improved quality, lower costs.

Industrial plastics with distinctive quality and performance:



STOCK SHAPES FOR MACHINING

Polypenco Nylon: rod, strip, tubular bar, plate, tubing
Polypenco Teflon*: rod, tubing, tape, sheet, spaghetti tubing
Polypenco Q-200.5: (cross-linked polystyrene): rod and plate
Polypenco K-51: (chlorinated polyether): rod, strip, tubular bar
. . . from The Polymer Corp. of Penna.



NYLAFLOW® PRESSURE TUBING

A specially processed flexible polyamide tubing for conveying air, gases or liquids.
. . . from The Polymer Corp. of Penna.

FERROTRON® Ferromagnetic Materials

A superior powdered iron filled plastic — available in rigid cores and flexible rod and tape.
. . . from The Polymer Corp. of Penna.

POWDERS For Molding And Processing

NYLATRON® specially compounded nylon molding powders.
NYLASINT® finely divided nylon powders for cold pressing and sintering.
WHIRLSINT+ coating powders for use in the Whirlclad Coating Process.
. . . from National Polymer Products, Inc.

WHIRLCLAD+ Coating Process

For the improved application of nylon, polyethylene and other coating materials to metals, ceramics, wood and other base materials.

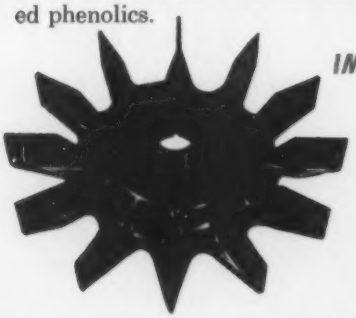
Creating a new product? Anxious to improve an old product? Getting breakage or failures in an existing product? Using costly die cast metals? Having corrosion problems?

Contact FIBERITE for the *right* reinforced phenolic or melamine. FIBERITE's experience and wide selection of formulations can solve your problems and reduce your costs.

Shown below are three new products molded from different FIBERITE formulations. All have replaced a die cast or fabricated metal part. Complete data available on request.

SAFE! New grain conveyor bucket won't spark...won't wear...keeps its shape ...won't rust or corrode



Maybe your product calls for excellent resistance to wear and high dimensional stability like this grain conveyor bucket. If so, you'll want to know more about F.M. 3510, one of FIBERITE's cotton fabric reinforced phenolics.

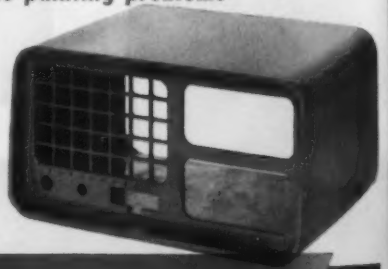
MOLDED OF F. M. 3510

Impact Strength	2.4 (Ft. Lbs. in Notch)
Flexural Strength	14,600 PSI
Tensile Strength	7,500 PSI
Dielectric Strength	275 (Dry) short time V/M
Specific Gravity	1.37 Molded

IMPROVED IMPELLER! forces air through electric motors... accurately molded in 7 sizes

MOLDED OF F. M. 1132

Impact Strength	1.7 (Ft. Lbs./ in Notch)
Flexural Strength	14,000 PSI
Tensile Strength	7,000 PSI
Dielectric Strength	300 (Dry) short time V/M
Specific Gravity	1.37 Molded



The advantages of molding this impeller of FIBERITE's cotton fabric reinforced phenolic F.M. 1132 include light weight, no static, won't bend or dent, will not cause a spark, and results in lower fabrication costs. Complete data on F.M. 1132 available on request.

NEW STRENGTH! new beauty in this intercom cabinet...eliminates painting problems

This intercom cabinet molded of FIBERITE's cotton fabric reinforced melamine 2015 is colorful and attractive, yet built to take abuse. Find out how this and other FIBERITE formulations can help you.

MOLDED OF F.M. 2015

Impact Strength	1.0 (Ft. Lbs./ in Notch)
Flexural Strength	16,000 PSI
Tensile Strength	7,000 PSI
Dielectric Strength	225 (Dry) short time V/M
Specific Gravity	1.52 Molded
Color	Any

ADD SALES APPEA

WITH Plaskon UREA AN

FOR SMOOTH, HARD, ENDURING SURFACES . . .

"MOLDED-IN" COLOR

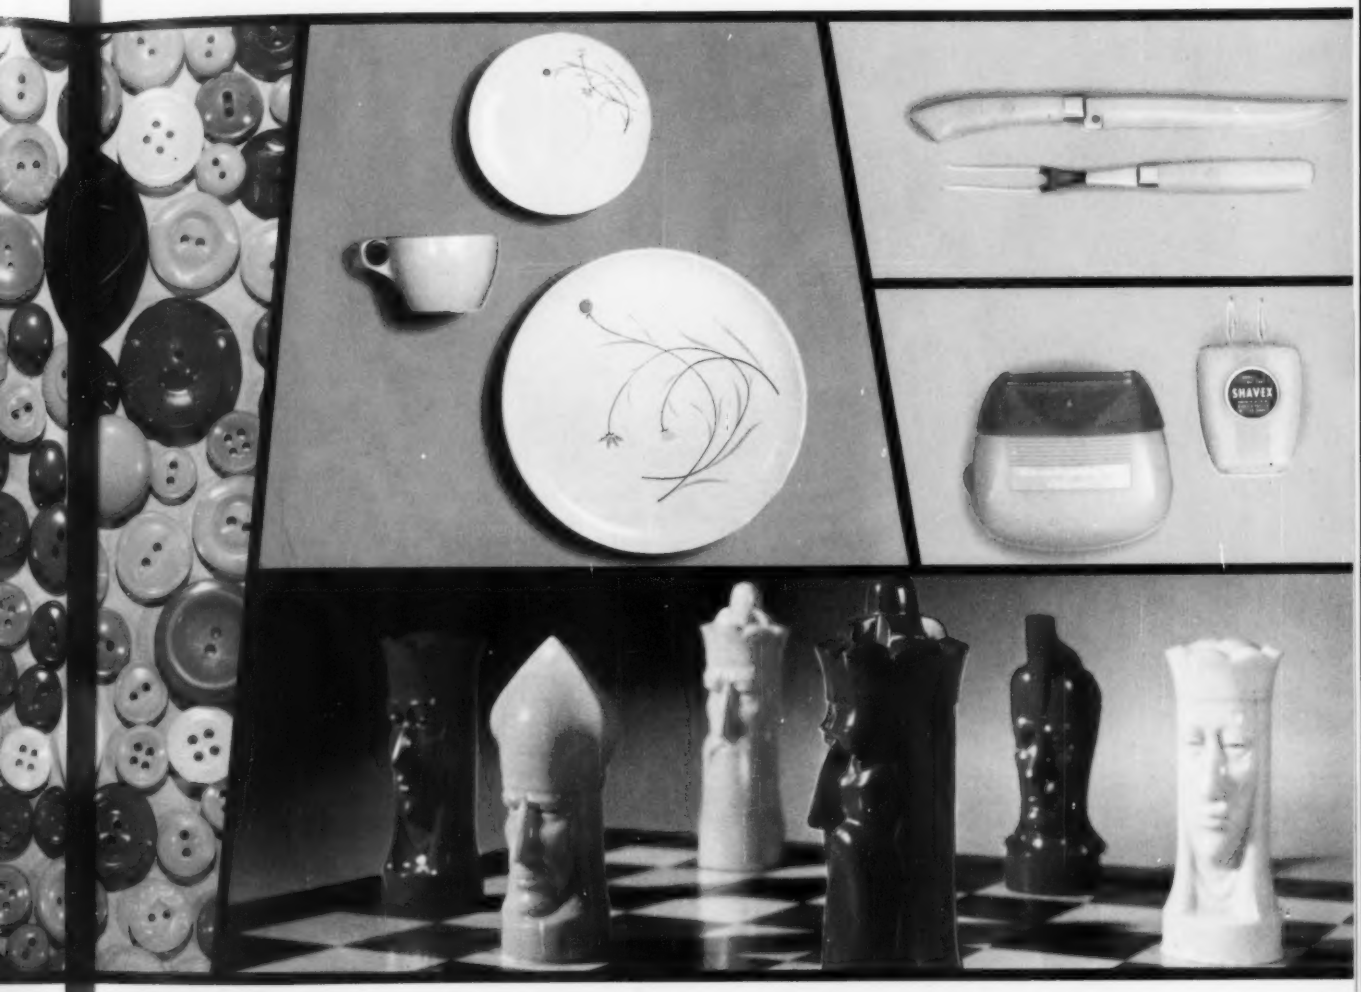
Nothing sells like color—especially when it's permanently molded into the product—virtually indestructible color that can't peel, chip or wear off. PLASKON Urea and Melamine offer complete freedom of color selection — over 12,000 colors!

HEAT RESISTANCE

These thermosetting plastics will not soften or discolor when exposed to elevated temperatures.

CHEMICAL RESISTANCE

Urea and Melamine effectively resist common organic solvents, soap, borax, oils and greases.



QUALITY

Pleasantness to the touch is an added sales appeal offered by products molded of Urea and Melamine. They feel warm and smooth, are non-electrostatic and will not attract dust or dirt.

For technical service, marketing counsel or more complete information on any PLASKON Molding Compound . . .

TO YOUR PRODUCTS

MELAMINE MOLDING COMPOUNDS

NOW IN MORE THAN 12,000 "MOLDED-IN" COLORS!

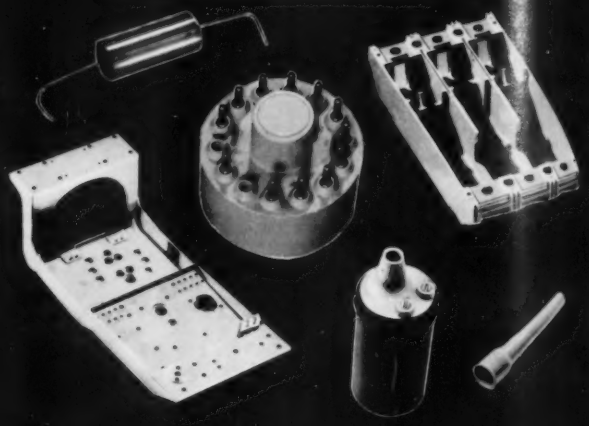
HIGH STRENGTH

Urea and Melamine products have extra hard, durable surfaces that resist scratching and chipping. Their rigidity and strength make them popular for a wide range of consumer and industrial products.

SUPERIOR ELECTRICAL PROPERTIES

PLASKON Urea and Melamine have high electrical insulation values and arc resistance—and are self-extinguishing. They provide a margin of safety and performance characteristics that allow greater freedom in the design of many new electrical products.

HOUSING TYPE UREA



The recent development of a Urea compound with easier moldability and greater fusibility makes possible the use of Urea in larger cabinet applications such as TV sets, business machines and air conditioners.

MOLDING AND EXTRUSION COMPOUNDS

Plaskon
ALKYDS
FOR CRITICAL ELECTRICAL PARTS

8200 FOR MOLDING

This type 6 nylon is noteworthy because of its amazing versatility. It possesses the most desirable properties of other type nylons—such as toughness . . . sterilizability . . . light weight . . . abrasion, corrosion and heat resistance . . . high impact strength. In addition, it offers many new advantages including:

1. *Better dimensional stability due to lower shrinkage, moisture expansion, thermal coefficient of expansion*
2. *Fewer voids during molding*
3. *Greater impact strength—with no loss in flexural or tensile strength*
4. *Can be molded in thin (up to .030") transparent sections*
5. *Can be colored more readily*
6. *Molds at lower cylinder temperatures*

PLASKON Nylon 8200 is being used in such hard working products as: gears, valves, cams, bearings, pipe fittings, shoe heels—and dozens more. Scores of new applications are still in the developmental stage.

8201 FOR EXTRUSION

PLASKON Nylon 8201 extrusion compound has the same exceptional properties as PLASKON 8200. Its low moisture content and wide range of permissible stock temperatures (450-550 F.) make extrusions run more smoothly. Its high molten viscosity facilitates the extrusion of tapes, film, shapes, rods and tubing in a wide range of cross sections.

A few of PLASKON Nylon 8201's present uses include: transparent film (can be vacuum formed), lubrication system tubing, fuel lines, wire coverings, window channels, tapes for stamping, monofilament. Several types are available to meet your specifications.

OUTSTANDING ELECTRICAL PROPERTIES

PLASKON Alkyds resist arcing better than any other thermosetting plastic material. And the dielectric strength of molded alkyd parts is exceptional. Alkyd parts also show a low loss factor and high resistivities.

EXCELLENT RESISTANCE AND DIMENSIONAL STABILITY

PLASKON Alkyds offer unexcelled dimensional stability due to their high degree of resistance to both moisture and heat. Alkyd parts will perform, without thermal degradation, at continuous exposures of 325 F. Once molded to specifications, no measurable after-shrinkage occurs.

AUTOMATION

Alkyds are suitable for use on high-speed automatic molding equipment . . . they mold four times faster than conventional thermosetting materials. Reinforced Alkyds require only medium molding pressures and non-reinforced Alkyds mold at very low pressures. All of these advantages add up to fast, economical production rates.

HIGH STRENGTH OF REINFORCED ALKYDS

The strength range of reinforced Alkyds surpasses that of any other impact thermosetting molding compound. They are easier to handle and cure more rapidly. In addition, resin and fibers remain practically inseparable during molding—even in thin-walled sections.

For full technical data, including specific performance characteristics, write: BARRETT DIVISION, Allied Chemical & Dye Corporation, 40 Rector Street, New York 6, N. Y. • HAnover 2-7300

Market ideas for reinforced plastics

GLIDPOL polyester resins . . . for strong, lightweight molded luggage!

You, as a fabricator, may find new markets for your production in these applications.

Want your share of a $200 million market? Then, investigate luggage, specifically matched-die molded luggage of fibrous glass, reinforced with GLIDPOL* polyester resins.

Stronger than steel but very lightweight, it outlasts other types, won't stain, mar or split. It's eye-pleasing, too, because pigmented GEL-KOTE* coatings provide a smooth, snag-free surface, plus permanent, fade-proof color. Another advantage: GLIDPOL resins allow great design flexibility, permit the assembly of complete matched sets from just a few basic shells.

Versatile GLIDPOL and GEL-KOTE resins are also used in the production of appliances, boats, vehicle bodies and hundreds of other products.

*A Glidden Trade-Mark

A request on your company letterhead will bring you a copy of Technical Bulletin MPE-57 which fully describes all of the Glidden GLIDPOL resins for casting, laminating, molding and coating.

BEETLE®

Urea-Formaldehyde alpha cellulose-filled Molding Compounds

Thermosetting

for properties see pages 6-7

BEETLE Molding Compounds produce marproof, lustrous moldings highly resistant to detergents, oils and greases. They are supplied in powder or granular form and various plasticities to meet specific molding needs in compression molding. Typical applications include radio cabinets, stove hardware, closures, electric appliance housings, wiring devices, cosmetics containers.

BEETLE is formulated to meet these specifications:

Federal L-P-406A, LC 726-1
ASTM D705-49, Grade I (Arc resistance limits are in process of revision by ASTM)

characteristics

Unlimited range of lustrous colors
Smooth, hard surface
Odorless and tasteless
Stain-resistant
Wear-resistant
Arc-resistant
Track-resistant
Dielectric strength
Durable

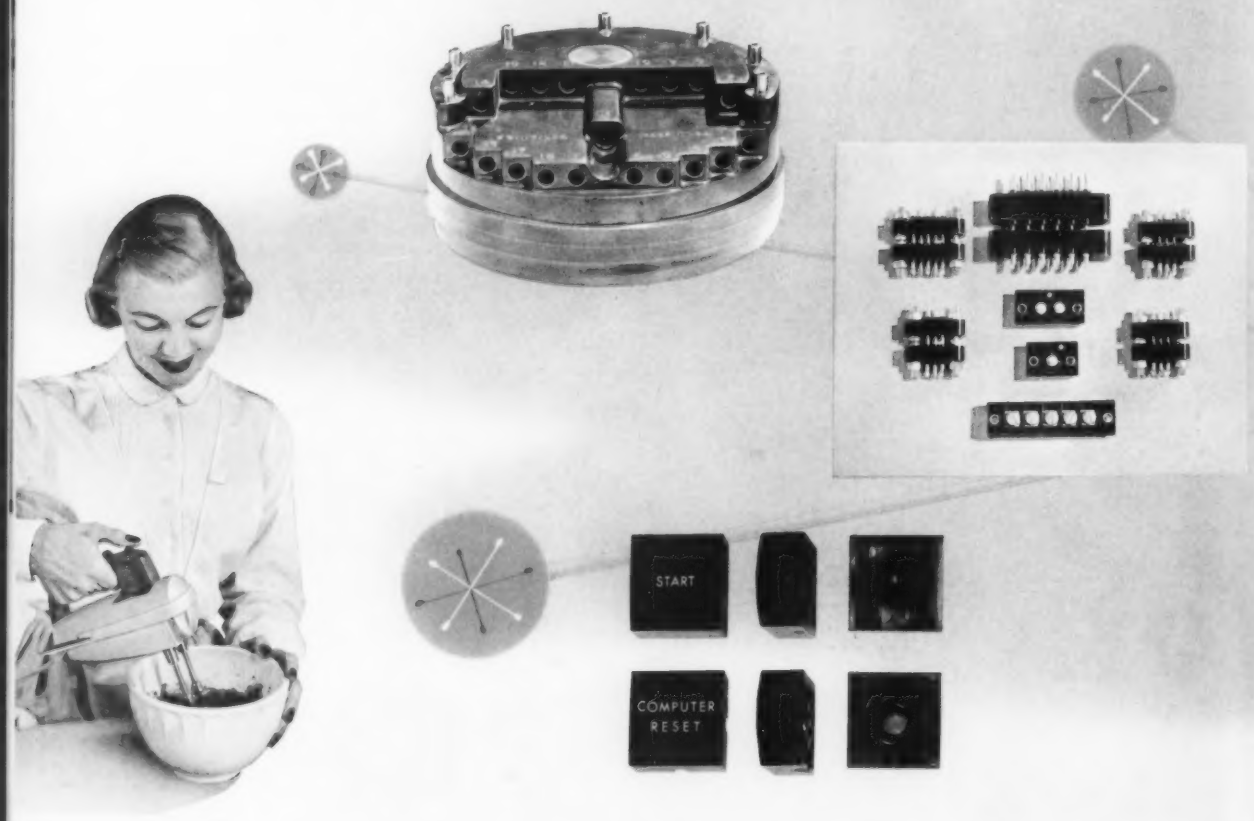
CYMEL *Molding Compounds are available in the following formulations to fill a variety of industrial and consumer applications. In general, they are suitable for compression, transfer or plunger molding.*

CYMEL 1077-1079
alpha cellulose-filled



Available in any color for molding such products as dinnerware, buttons, electric mixer and shaver housings. Characteristics: Break and heat resistance; extraordinary surface hardness; rich, lustrous look and feel; excellent chemical resistance; excellent electrical properties, including arc and track resistance.

CYMEL 592
asbestos-filled

Available in brown only for electronic equipment, aircraft and automotive ignition parts, circuit breakers. Characteristics: Excellent arc resistance and dielectric strength at elevated temperatures; dimensional stability; resistance to atmospheric extremes.

CYMEL 1500
wood flour-filled

General purpose arc resistant, electrical grade material for watt-hour meter blocks, automotive ignition parts. Characteristics: Exceptional arc resistance, excellent dielectric strength. Brown only.

CYANAMID

CYMEL®

b

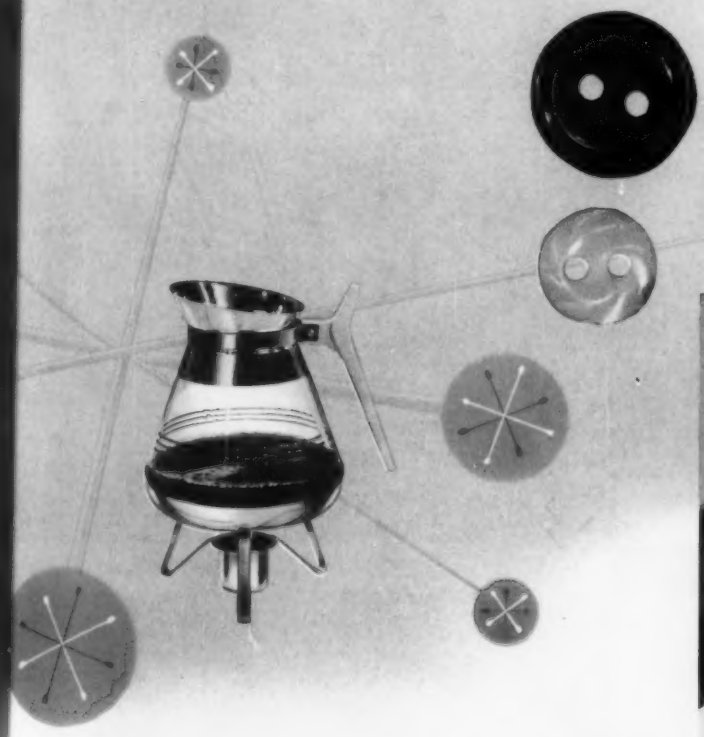
CYMEL 1502
cellulose-filled

Arc resistant, electrical grade material for connector plug inserts, circuit breakers, automotive ignition parts. Characteristics: Particularly good dimensional stability, dielectric strength. Insert retention is excellent. Brown only.

CYMEL 3135
glass fiber-filled

Electrical grade material with high impact resistance, extraordinary flame resistance, excellent arc resistance, low shrinkage and moisture absorption. Natural color..

CYMEL 3136
granular glass-filled



Electrical grade material with intermediate strength, excellent arc and insulation resistance, extraordinary flame resistance, low shrinkage and moisture absorption. Natural color.

CYMEL 3020
chopped cotton fabric-filled

Ideal for products requiring resistance to impact as well as heat and chemicals. Good arc resistance. Black only.

CYMEL 404
unfilled

Highly translucent, granular material for decorative effects. Used principally for button and jewelry findings.

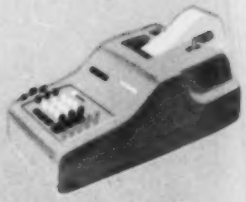
CYMAC®

Methylstyrene Molding Compounds

Thermoplastic



These compounds are so heat-resistant that molded products show no distortion after repeated immersion in boiling water. These thermoplastic compounds may be injection-molded in any equipment designed for their polystyrene counterparts.

CYMAC 400 *Polymethylstyrene*

Offers resistance to heat up to 212°F. plus all the desirable properties of polystyrene: excellent electrical properties, clarity, luster, and unlimited range of transparent and opaque colors. They resist the high operating temperatures encountered in automatic dishwashers, sterilizers, automobile interiors, radios and store display windows. Applications include housewares, hospital equipment, refrigerator trays and containers, nursery products, brush backs and bristles, radio cabinets, battery cells, display fixtures. CYMAC 400 is available in crystal clear, Bureau of Standards colors and an unlimited range of custom colors, transparent and opaque.

CYMAC 201 *Methylstyrene-Acrylonitrile Copolymer*

In addition to the unusual heat resistance of CYMAC 400, CYMAC 201 offers better toughness and an increase in resistance to abrasion, crazing, and attack from chemicals, acids and oils. These characteristics point to picnic and kitchen ware, airline dinnerware, business machine housings, fan blades, packaging, pen barrels. Insert retention is excellent. Available in light straw, ice tint, and an extensive range of transparent and opaque colors.

LAMINAC®

Polyester Resins

Each of these thermosetting resins has been formulated to provide the best combination of properties for specific applications. With the exception of a few special types, they are clear, nearly colorless liquids. They vary in viscosity, rate of cure, degree of reactivity and in degree of rigidity of the cured product.

Parts can be molded by hand lay-up using a casting technique, or by compression molding with heat and pressure. The reinforcing agent most commonly used is fibrous glass, but a wide variety of fillers can be used—paper, rayon sisal, felt, etc. Flexible or rigid laminates can be produced by the proper choice of resins. Curing temperatures range from normal room temperature to 300°F, while pressures may vary from 0 to 1000 psi.

characteristics

Light weight
Great strength
Impact resistance

AMERICAN CYANAMID COMPANY
Plastics and Resins Division

CYMEL®
CYZAC*

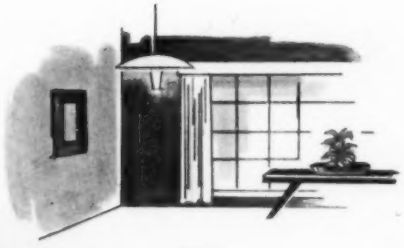
Laminating Resins

Thermosetting

For decorative laminates: ***Furniture, counters, wall panels and similar decorative laminates utilize wood veneers, paper or fabric. Impregnation with CYMEL Resins makes them exceptionally hard, strong and resistant to heat, moisture and chemicals.***

For industrial laminates: ***Glass cloth, canvas or asbestos are usually used for industrial grade laminates. Advantages include resistance to heat, flame, electrical arcing, and chemicals, especially alkalis.***

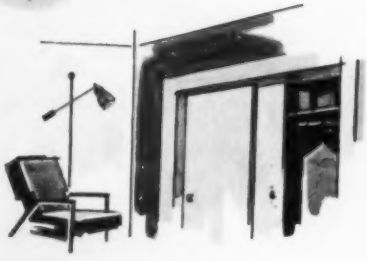
CYMEL 405



An unfilled melamine-formaldehyde resin in the form of a free-flowing dry white powder. This resin is also suggested for various other uses such as water-resistant thermosetting binders, hardeners for polyvinyl alcohol and polyvinyl butyral, strengthening agent for plaster of Paris, and any other applications that can be aided by the addition of a water-soluble, low-reacted form of heat-setting melamine-formaldehyde resin.

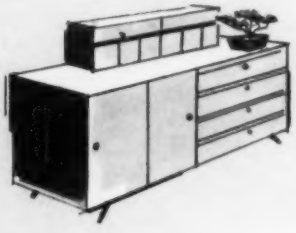
CYMEL 430

Melamine-formaldehyde powdered resin modified with an unusually effective plasticizer or flow promoter. It is used chiefly in treating overlay and print sheets in decorative laminates and exhibits many advantages over the straight or unmodified melamine resins.

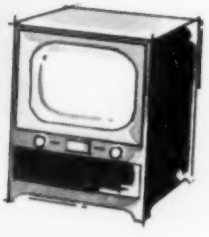


*Trademark

CYZAC Laminating Resins make it possible to produce, directly on low-density particle board and on hardboard-faced plywood, finishes and surface characteristics approaching those of high-pressure decorative laminates. Laminated surfaces produced with CYZAC resins have exceptional craze resistance when subject to heat or strains caused by dimensional changes in the core material. Both resins are solutions packaged at 55% solids content.



CYZAC 2247



Formulated for impregnating print-grade laminating papers to produce decorative surfaced hardboards for use as wall panels, door panels, cabinets, do-it-yourself applications, low-cost furniture, TV cabinets.

CYZAC 2352

Provides the most satisfactory characteristics in impregnated overlay-grade laminating papers. Laminated directly to wood surfaces at moderate cost, these papers produce a transparent, colorless finish with excellent surface properties; they may even be applied over stained surfaces. The finish gives exceptional beauty and durability to flat working surfaces of tables, dressers, desks and chests. CYZAC 2352 also offers new ease of handling and application in production of prefinished lumber products at lumber mills.

CYMEL®
MELURAC®
URAC®
KETAC®

Adhesive Resins

Thermosetting

CYMEL

NO. 401
Hot press melamine-formaldehyde plywood adhesive for use with or without fillers. May be added to urea resins to improve durability of bond and materially lengthen working life of glue mix. Also used for laminating heavy timbers in marine applications and for general-purpose work where a boil-resistant, non-staining bonding agent is required.

NO. 421
A powdered melamine-formaldehyde resin for use as fortifier of plaster of Paris and gypsum to increase structural strength of cast products.

MELURAC

NO. 255
Powdered melamine-urea-formaldehyde resins, two-package, formulated solely as an adhesive for tapeless splicing of veneers.

NO. 259
Newly developed, one-package, melamine-urea-formaldehyde resin for tapeless splicing of veneers, requiring addition only of water.

NO. 300
Melamine-urea-formaldehyde, one-package, fast-curing colorless powdered resin for hot pressing flat or molded plywood. Combines non-staining, moderate cure temperatures, durability, boil resistance. Ideal for exterior-grade plywood. New catalysts reduce cure rate to that of hot-press urea resins.

NO. 301
Powdered melamine-urea-formaldehyde resin without filler.

NO. 304
A melamine-urea-formaldehyde resin developed expressly for use as a particle board binder. A fine, free-flowing powder that is easily handled. Imparts no color to the particle board. May be blended dry or sprayed from water dispersion into wood chips or sawdust.

URAC

NO. 180
General-purpose, urea-formaldehyde resin in water solutions. Catalysts and hardeners are available for all wood-bonding applications—cold or hot press plywood gluing, high-frequency gluing, fortification of starch-dextrine adhesives, etc. High solids solution (66% P.M.M.A. Method) for drum, tank-car or truck shipments.

NO. 186
Similar to URAC 180, but containing 60% resins solids.

NO. 185
Craze-resistant urea-formaldehyde adhesive for assembly or secondary gluing operations. Two components—liquid resin and powdered hardener. Sets at room temperature with low pressure. Excellent for bonding decorative laminates, Masonite and other hardboards.

NO. 110
Similar to URAC 180, but in powder form containing no inert materials. Catalysts are available for general-purpose wood gluing—cold or hot setting.

KETAC

NO. 1156
A liquid ketone-formaldehyde resin. Alkaline curing, it was formulated especially as a fortifier of starch adhesives used in the manufacture of corrugated paperboard.

gluing-to-standards guide

OP.19/A

CHEMICAL
GOODYEAR
DIVISION

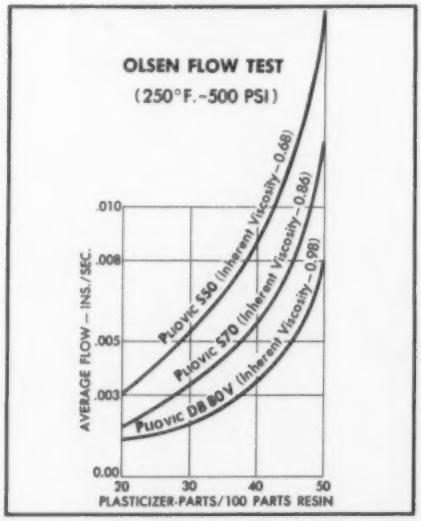
The first PLIOVIC resin was introduced in 1947.

Today, many years and many new resins later, there is a select family of PLIOVIC resins, each designed to fulfill a specific need for quality vinyl products.

The success of the PLIOVIC resins can be measured by their steady growth. And it stems from a constant effort in research, in development, and in production to supply industry with top-notch materials.

The happy part of this story is that it really has no ending. Through continuing effort, more new resins and more plant expansions shape the trend for the future.

Equal in importance to product quality in the success of PLIOVIC is the service accompanying its sale. Competent technical assistance, comprehensive product literature, as well as effective processing and shipping of orders, are basic tenets of Chemical Division operation.



The growing list of PLIOVIC customers indicates it's a good way of doing business, too.

CHEMICAL
GOODYEAR
DIVISION

Two newcomers to the PLIOVIC family:

Two of the latest results of Goodyear's constant development effort are PLIOVIC S50 and PLIOVIC S70. Both meet the processing needs of the industry, without sacrifice of end properties.

Plastic Flow of PLIOVIC S50 vs. Other Vinyl Resins

PLIOVIC S50 is an unmodified polyvinyl chloride resin of very low viscosity. It exhibits many of the desirable processing characteristics of copolymer resins, while approaching the physical properties and heat stability of unmodified, higher molecular weight resins.

Compounds based upon PLIOVIC S50 have superior plastic flow properties, can be processed at temperatures as much as 50°F. lower than average molecular weight resins, and process easily with little or no liquid plasticizers. These advantages suggest the use of PLIOVIC S50 in blends with higher molecular weight resins, as a replacement for copolymer resins or as the base resin in critical molded, extruded or semirigid calendered items.

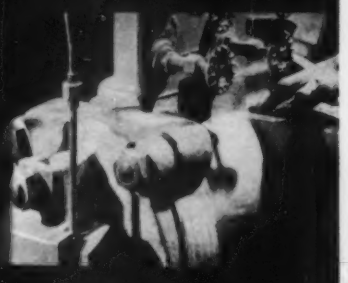
Crystal-Clear Sheeting Made with PLIOVIC S70

PLIOVIC S70 is a medium viscosity, general purpose, polyvinyl chloride resin. Its viscosity, combined with a fine particle size, is ideally suited to conventional compounding techniques and shows particular advantage in improved flow at moderate temperatures.

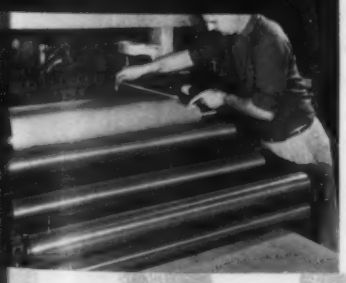
The processing advantages of PLIOVIC S70 especially qualify it for use in calendered goods where it exhibits sparkling clarity, excellent surface, good gauge and color uniformity and excellent heat sealability. However, PLIOVIC S70 can also be used to advantage in critical molded and extruded applications or to "temper" high modulus stocks.

CHEMICAL
GOODYEAR
DIVISION

The established members of the PLIOVIC family:



Here are the older members of the PLIOVIC family—resins which through their wide acceptance have proved the worth of continual effort toward improvement in product and service:



PLIOVIC AO—one of the first of the family—is a unique copolymer with particular application in dispersions. Its fine, soft particles solvate readily, disperse thoroughly with minimum mixing. PLIOVIC AO also tolerates high percentages of extender plasticizers. Moreover, it fuses at low temperatures, providing longer product life through a shorter heat history. Principle applications for this resin include fabric coating, metal coating, and slush or rotational molding.

PLIOVIC DB90V is a high molecular weight polyvinyl chloride as evidenced by its inherent viscosity of 1.09. It possesses the properties characteristic of unmodified vinyl polymers: high strength, a high degree of flexibility when plasticized, full color possibilities, flame resistance, and relative inertness to chemicals, wear, weather and age. The processability and end properties of PLIOVIC DB90V recommend this resin for both extruded and calendered products.

PLIOVIC DB80V is a lower molecular weight polyvinyl chloride resin with an inherent viscosity of 0.98. A general purpose resin, it exhibits properties typical of unmodified vinyls. Where limitations are imposed on processing temperatures, PLIOVIC DB80V allows development of excellent physical properties at somewhat reduced temperatures. Primary application for the resin is in the production of calendered film and sheeting.

PLIOVIC EDB90V is very similar to PLIOVIC DB90V with one important exception—it has passed the rigid tests of Underwriters' Laboratories, Inc., and has been placed on their resin interchangeability list. Thus, PLIOVIC EDB90V combines excellent electrical properties with very good processing and physical property characteristics. It finds application in many types of wire insulation.

Rogers impact phenolics quality-controlled

FOR AUTOMATIC LOADING

Rogers medium and medium high impact phenolics for automatic molding are the result of a development program with manufacturers of automatic molding equipment. Produced under rigid statistical quality control methods, these compounds feature consistent uniformity in pourability and are so clean as to be virtually dust-free. These advantages are coupled with a fast rate of cure, a low bulk factor of 3.5 to 1 and good to excellent molded appearance.

Uniform apparent density of Rogers impact phenolics for automatic molding assures the right charge every time for automatic volumetric loading or preforming. Absence of dust eliminates arcing during pre-heating. Although created for automatic molding, these Rogers materials offer many advantages for conventional molding techniques. *Write to Dept. PE for data sheets or ask to have one of our technical representatives review our materials program with you.*

MONSANTO PLASTICS FACT FILE

MONSANTO

The World's Largest Family of Plastics

MONSANTO MOLDING COMPOUNDS

LUSTREX styrene plastic

Monsanto Lustrex is one of the lightest and most widely used thermoplastic molding materials. It is hard, rigid, with high dimensional stability, good chemical resistance, high dielectric strength, tasteless, odorless, and non-toxic. Lustrex can be molded to sharply defined detail and finish.

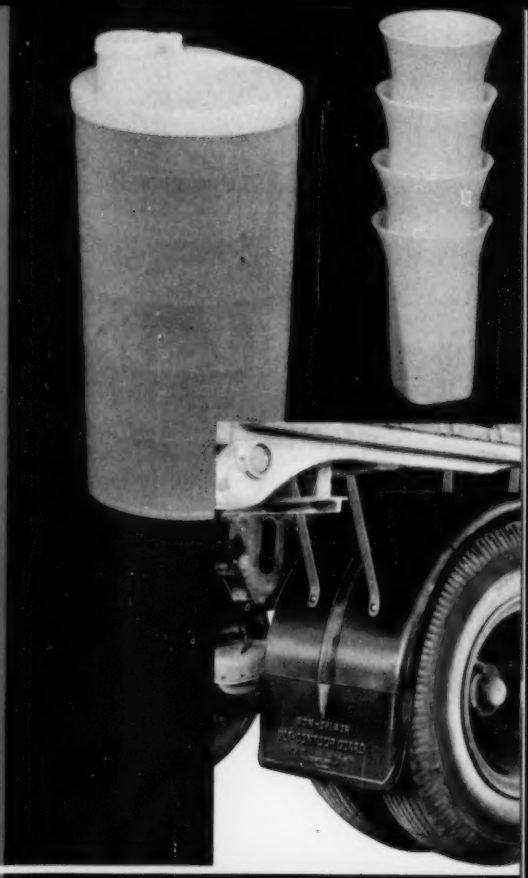
Available in a broad range of transparent, translucent, and opaque colors, as well as crystal. Molding compounds for compression, and injection molding, and extrusion in all types of machines and molds. Extrusion formulations suitable for vacuum forming.

There are special formulations in various flows and set-ups: for general purpose applications—the "Balanced Line" comprising Lustrex Hi-Flow 55 (improved flow), Lustrex Hi-Flow 66 (long flow, moderate set-up), and Lustrex Hi-Flow 77 (good flow, fast set-up); rubber modified formulations for applications requiring medium and high impact strengths—Lustrex LHA (medium impact, high degree of translucency), Lustrex Hi-Test 88 (high impact), and Lustrex Hi-Test 88B (extrudable, high impact, high degree of translucency); for applications requiring heat resistance—Lustrex Hi-Heat 99 (heat resistance up to 204° F.), Lustrex Hi-Test 89 (heat resistant, high impact) and LXC, a super heat resistant styrene copolymer with heat resistance up to 217° F.; and for applications requiring fluorescent light stability, all general purpose formulations are available in Lustrex Permatone.

APPLICATIONS:

refrigerator parts
toys
packaging
air conditioner cabinets
radios
housewares
wall tile
phonograph records
television components
displays
electrical equipment

MONSANTO MOLDING COMPOUNDS



Monsanto *Polyethylene* T.M.

APPLICATIONS:

housewares
toys *packaging*
industrial parts
"squeeze" bottles *vials*
closures
molded liners

One of the newest of the thermoplastics, polyethylene is already one of the most useful and versatile. Polyethylene molded products made from Monsanto Polyethylene resins are tough, resilient, with high impact resistance. They are flexible over a wide temperature range, with extremely low dielectric constant and low power loss factor. They are chemically inert, non-toxic and odorless.

Available in pelleted molding compounds for injection, compression or blow molding over a wide flow range 1.2-22 melt index. Readily processed in a broad range of colors.

RESINOX phenolic

APPLICATIONS:

electrical switch gear
ignition parts for automotive, aircraft, and outboards
TV and radio cabinets
caps and closures *furniture drawers*
appliance components and handles
wiring devices *washing machine agitators*
telephone hand sets *camera parts*
caster wheels
water pump impellers

Monsanto Resinox molding materials are themosetting plastic compounds based on phenolic resin. All molded Resinox parts are characterized by inherent color and finish, resistance to heat, and broad adaptability in design.

A broad range of standard formulations are available for parts requiring high impact and tensile strength, exceptional electrical insulating properties, resistance to high heat, water, acids, alkalis, and other chemicals, or meeting rigid odor and taste requirements.

Six types of Resinox compounds are supplied for compression; transfer or automatic molding: general purpose, impact-resistant, electrical grade, heat-resistant, chemical-resistant, and closure compounds.

MONSANTO MOLDING COMPOUNDS

RESIMENE melamine

APPLICATIONS:

electrical, electronic, and radar equipment
circuit breaker parts *terminal blocks*
connectors *insulating tubes*

Thermosetting molding compounds with cellulose fillers for compression and transfer molding. Recommended for applications requiring high arc resistance, extreme hardness and durability, and excellent resistance to heat and alkalis.

OPALON vinyl chloride

APPLICATIONS:

appliance parts *toys* *masks* *cord plugs*
goggles *coil forms* *knobs*
grommets *sporting goods* *handles* *housings*
swim accessories *wiring devices* *electrical system*
components *housewares* *phonograph records*

Opalon thermoplastic molding powders are supplied in granular form and as dry, free-flowing dustless powders for injection and compression molding. They have outstanding heat stability, moldability, short molding cycles, low shrinkage.

MONSANTO FABRICATING MATERIALS

POLYFLEX* 100

styrene film and sheeting made of Monsanto Lustrex

APPLICATIONS: *packaging printing metalizing decorative laminating overwrapping light diffusers protective laminates signs displays*

Polyflex 100 is a biaxially oriented styrene sheet made of Monsanto Lustrex for use in the manufacture of up-to-date, self-selling packaging, items for the home, decorative laminating and many other applications. Can be blanked, metalized, printed or folded and may be combined with many other materials. Available from stock in roll form in light gauges from .001" through .020" in 21" and 42" widths. Ranges from water clear to opaque with wide variety of color.

*POLYFLEX, T.M. Reg. U.S. Pat. Off. Plax Corp. Licensed to Monsanto Chemical Company

VUEPAK cellulose acetate film

APPLICATIONS: *transparent windows wallet-envelopes fabricated parts filing tabs protective laminates transparent inserts diagrammatic drawings rigid containers displays canisters protective envelopes*

Vuepak is a crystal clear rigid film that can be formed into boxes and containers of outstanding beauty and sales appeal. Available in continuous, untrimmed and slit-to-size rolls up to 60" wide and up to 2000' long, in thicknesses from .005" to .020". Also in stock size sheets.

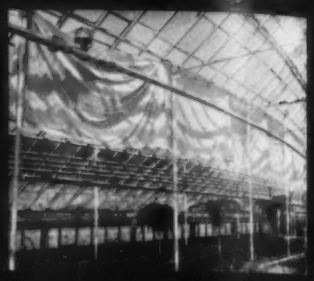
Vuepak is adaptable to many fabricating methods—shaping, drawing, folding, and scoring. It can be printed, embossed, stapled, or cemented.

NITRON cellulose nitrate film

APPLICATIONS: *optical frames cutlery handles toilet seats hamper tops piano keys*

Nitron is a thermoplastic sheet with exceptional toughness, beauty and pattern variety. It is resilient, but not elastic, resists weak acids and alkalis.

Available in many colors and patterns, Nitron can be fabricated by any standard method—blow-molded, stamped, heat-formed, or machined. It is supplied in 20" x 50" sheets of various thicknesses.



ULTRON vinyl film

APPLICATIONS:

draperies *machine covers*
shower curtains *table cloths*
rainwear *wall coverings*
inflatable items
moisture vapor barriers
laminating

Ultron film is noted for uniform gauge, color clarity, pliability, good drape, and dry resilient hand. It is tough, long-lasting, resistant to mold and mildew, and will not fade or stain easily. Tasteless, odorless, non-toxic.

Available in a wide range of transparent and opaque colors, and in embossed patterns with fabric-like texture and appearance. In gauges up to .020", widths up to 72". Special formulations are available for industrial and agricultural applications.

Ultron film can be heat sealed and cemented, printed, embossed or molded.

ULTRON vinyl sheet

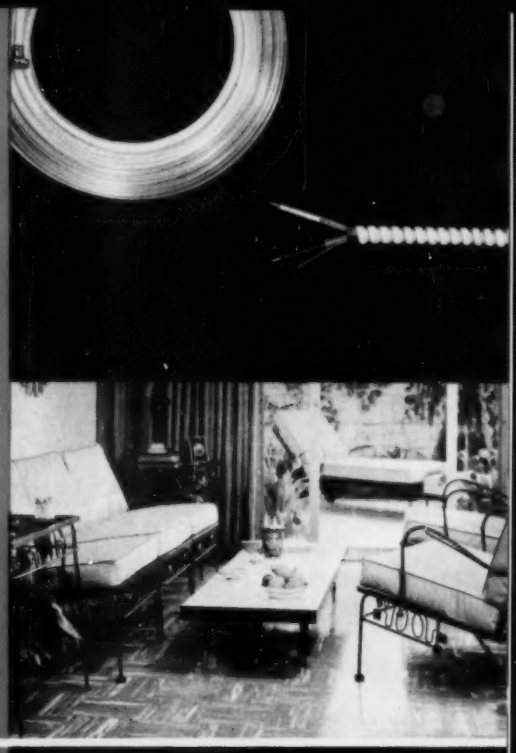
APPLICATIONS:

printing stock *translucent ceilings*
vacuum forming *electrolyte molds*
printing plates *displays*
drawing instruments
light-diffuser panels *calculators*
lamp shades *Christmas lighting displays*

Ultron rigid vinyl sheets and rolls are distinguished for their dimensional stability, mechanical strength and toughness, high softening temperature, flame resistance, excellent light stability, and resistance to chemicals.

Rigid Ultron is available in rolls from .0075" to 0.020", and in widths up to 75"; also in sheets 21½ x 51½" untrimmed in gauges up to 125". Greater thicknesses upon request. Matte, calender, and high polish finishes. Ultron sheets can be printed, die-cut, machined, vacuum-formed, cemented, hot air welded, electronically sealed, embossed, planished, laminated and corrugated.

MONSANTO EXTRUDING AND CALENDERING MATERIALS



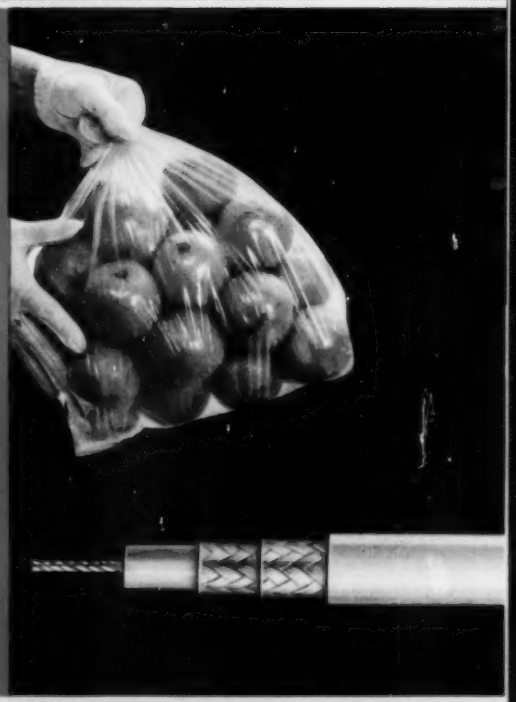
OPALON vinyl chloride resins

Opalon 300, 300FM and 330FM resins are supplied for calendering and extrusion operations and are especially recommended for the dry blending process. They provide exceptional color depth, uniformity, toughness and flexibility at low temperatures.

Special compounds supplied as granules or dry blend for wire and cable insulation, profile extrusion and molding are also available. Excellent for use in the manufacture of rainwear, garden hose, upholstery, fabrics, etc.

Opalon 505 and 510 copolymer resins are widely used in manufacturing floor tile and phonograph records, where ease of processing make these resins particularly suitable.

Opalon 410 is a specially developed paste resin for vinyl plastisol compounding. It is supplied as a "stir-in" powder and increases speed and ease of preparation. Widely used for fabric coating, slush moldings, dipping operations, foams and sponges.



Monsanto

Polyethylene resins

T. M.

In pellets—natural or colored—Monsanto Polyethylene resin may be extruded as film and sheeting, wire insulation, piping, tubing, and profile shapes. Can be calendered into film and sheeting and laminated immediately or in subsequent operation. Non-slip and slip grade formulas available over broad melt index range.

MONSANTO LAMINATING MATERIALS

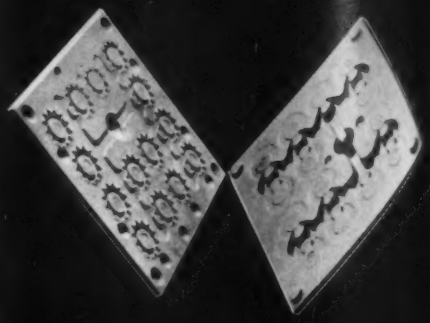
SAFLEX vinyl butyral

A continuous adhesive film in clear or colored, as well as graduated color, forming the interlayer for laminating safety glass. Also used for TV implosion plate laminates, and decorative applications.

MONSANTO INDUSTRIAL RESINS

for bonding

RESINOX phenolic



Resinox phenolic resins are widely used as a coating or bonding material for Resinoid grinding wheels, clutch facings, brake linings, coolant and heat-resistant sand paper. Mechanical paper base separators for automotive batteries. Paper and felt base filters for oils and chemicals. Bonding material (with Resimene melamine resin) for glass and rock wool thermal and acoustical insulation and other industrial applications. Available in liquid and dry-powdered form.

for foundry

RESINOX phenolic

Resinox phenolic resins have been specially developed as hot and cold-coating resins for sand in production of shell molds and cores. They are non-dusting, free flowing, with rapid cure.

LYTRON resins

Synthetic resins used as thickening agents in powder form for foundry sand and wash water clarification systems. Lytron reduces clay balling, improves sand workability and packability for better molds for metal castings.

for laminating

RESIMENE melamine

Resimene resins are colorless and color stable, hard, durable, and scratch-resistant, heat and flame-resistant, and chemical-resistant. Available in water-alcohol, soluble, spray-dry powders, they form laminates with paper, cloth, glass and asbestos fibers that provide a beautiful durable surface for all types of furniture, counter tops, cabinets and walls in kitchens and bathrooms. Industrial melamine laminates have high electrical arc resistance and fire resistant properties.

RESINOX phenolic

Supplied in water or alcohol solutions for treating laminate filler materials—paper, cloth, wood veneers, glass, or asbestos fiber. Resinox laminating resins are tough and durable, resist acids and weak alkalis, display good heat resistance up to temperatures of 300-350° F. Used in manufacture of decorative core stock and electrical grade laminates for radio and TV and most home electrical appliances. Also in gears, ball-bearing races, pulleys, bushings, for light and heavy machinery, cars, planes and ships.

ONSANTO TO TEXTILE RESINS

Monsanto supplies a complete line of resins and catalysts for textile finishing and sizing. These provide shrinkage control and washability, lively hand, wrinkle resistance and durability, and improve finish of woolens, cottons, rayons, and other synthetics. Monsanto catalysts speed resin cure so that full effect of resin treatment is obtained.

RESLOOM melamine resins

Series of essentially monomeric melamine resins—liquids or powders. Impart shrinkage control, wrinkle resistance and textural effects to cottons, rayons, synthetics and wools.

RESLOOM E-50 cyclic ethylene urea formaldehyde resin

Supplied as 50% solids cyclic ethylene urea formaldehyde resin in liquid form. Permanent textured effects, dimensional stability, wrinkle resistance or "wash 'n' wear" finishes to cottons, rayons and other synthetics.

LYTRON resins

Unplasticized polystyrene emulsions. Furnish durable finishes without curing or after treatment.

STYMER resins

Stymer LF—vinyl resin soluble in ammonium hydroxide. Stymer S—styrene copolymer resin, soluble in water. Sizes for acetate filament yarns.

CATALYSTS

Four organic catalysts comprise the Monsanto series for textile applications. Provide rapid efficient cure of melamine and cyclic-urea resins to give rayons, cottons and synthetics full effect of resin treatment.

ONSANTO PAPER AND COATING RESINS

Monsanto supplies the paper industry with a line of resins that produce wet strength papers of all types; also resin surface-sizing for improved surface characteristics and excellent printability on various specialty papers and paper board.

OPALON vinyl chloride paste resins

Opalon resins are used in coating cloth and paper. They provide tear strength, low temperature flexibility, and resistance to weathering, aging.

Monsanto Polyethylene resins

As wax reinforcement coatings, Monsanto Polyethylene resins give paper or board coatings a higher gloss, greater scuff resistance, stronger heat seals, improved printability.

SCRIPTITE resins

Scriptite 33 is a melamine-type resin supplied as dry powder and Scriptite 40 is urea type supplied as transparent colloidal solution for creating highly improved wet strength paper. Scriptite 50, 52, and 54 are polyelectolyte resins supplied as dry powder, which dissolved in water, add improved surface characteristics and printability to paper products.

MONSANTO ADHESIVES

A comprehensive list of adhesives that include urea, melamine, phenolic, and resorcinol resins under the trade names of Lauxite and Resinox, and casein and soybean adhesives trade-named Lauxein.

Lauxite and Resinox are recommended as cold-setting adhesives and glues for exterior and interior plywood, furniture. Also used in laminating wood-arches, beams, edge gluing of lumber and door assembly work. Special line for chipboard industries, granulated wood compression molding.

LAUXITE urea and melamine resins

Dry powders and liquids for hot and cold pressing, radio frequency equipment, weather-resistant, quick-setting, high gluing strength.

RESINOX phenolic and resorcinol resins

Dry powders and liquid for cold pressing, hot pressing, and granulated wood molding. Durable water-proof bonds.

LAUXEIN casein and soybean adhesives

Bonding and cold-setting glues for low temperature applications and water-resistant glue bonding. Also used in Monsanto's NO-CLAMP Process for making plywood, doors, lamination work, and many types of wood gluing. For interior type plywood, laminated arches and beams, doors, furniture, cabinet-making, nail-pressure gluing.

MONSANTO INTERMEDIATES

STYRENE MONOMER

Liquid inhibited with TBC. For styrene molding compounds, synthetic rubber, copolymers, ion exchange resins, polyesters; also styrene modified oils and alkyds for surface coatings.

VINYL CHLORIDE

Liquefied gas inhibited with phenol. For the manufacture of polyvinyl chloride resins, compounds, copolymers, and chemical intermediates.

ACRYLONITRILE

Liquid inhibited with Monsanto MQ inhibitor. Uses include production of synthetic textile fibers, nitrile synthetic rubber, copolymers, and chemical intermediates.

FORMALDEHYDE

37% aqueous solution inhibited with methanol. For preparation of melamine and phenolic resins; preservative, disinfectant, and is a chemical intermediate.

MONSANTO SURFACE COATING RESINS

Monsanto supplies a large group of melamine, urea, phenolic, and styrene resins for paints, varnishes, and lacquers. Monsanto also supplies latices for use in the production of interior and exterior paints, and thickening agents for latex paints and compounded rubber latex products.

RESIMENE Melamine and urea-formaldehyde resins in organic liquid solution for baked enamel and industrial finishes. Impart improved soap resistance, surface hardness, faster cure, better gloss, weathering, alkali- and chalk-resistance, color retention to protective finishes for appliances, automobiles, and other fabricated metal items.

RESINOX Phenolic liquid solutions for baked enamels and industrial finishes. Imparts high heat resistance, good chemical resistance for can, drum, and tankcar linings, special primers, chemical resistant coatings, wire coatings.

LYTRON Polyelectrolyte thickening agents in powder form for latex paints and compounded rubber latices. Lytron alkali-soluble resins are used to stabilize, harden, thicken and promote adhesion in water and latex coating systems.

LYTRON Plasticized or unplasticized latices as main vehicles for latex paints and as modifiers in compounding rubber and other latices.

Where creative chemistry works wonders for you

Engineered Resins
For Modern Industry...

National Polymer Products, Inc. offers you complete service for:

NYLATRON® GS
Nylon Molding Powder

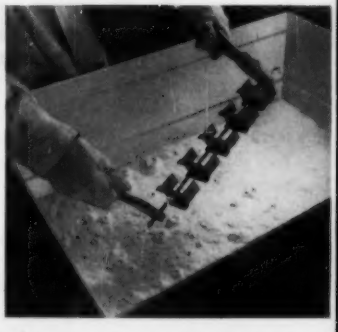
. . . a molybdenum disulphide filled nylon† that is expanding the usefulness of nylon by providing parts with greater rigidity, higher heat distortion temperatures. Molybdenum disulphide — a dry lubricant — adds low surface friction, high wear and abrasion resistance with less warpage and better tolerance control in molding.

† Patents Applied For

NYLASINT® Nylon Powders
for Cold Pressing and Sintering

. . . finely divided nylon powders specially processed with various inert fillers (such as graphite, molybdenum disulphide, etc.) that provide superior properties such as low surface friction and outstanding dimensional stability for bearings, bushings, cams, rollers, gears and similar parts. Cold pressed and sintered Nylasint parts are available through licensees.

WHIRLSINT* Powders



. . . a family of finely divided powders developed for use with the Whirlclad* Process — a new method of applying coatings of resinous materials on metals, glass and ceramics, etc. These Whirlsint Powders consist of:

Whirlsint Nylon
Whirlsint Ethylene
Whirlsint Polyether K-51
Whirlsint Epoxy Resins
Whirlsint Cellulosic Powders
Whirlsint Vinyls

— plus other powders now being tested and evaluated.

The Whirlclad Process is available to licensees in the United States and Canada from Polymer Processes, Inc., an affiliate of National Polymer Products, Inc.

* Polymer Trademarks

National Polymer resins are produced under rigid quality controls to assure consistent, uniform high quality. Write today for detailed performance data or help with your particular application.

IF YOU ARE a designer, molder, extruder or user of plastics, count on Koppers for high-quality polyethylenes and polystyrenes. In addition to quality products, Koppers offers the services of experienced plastics technicians. These well-versed technical men are stationed in or near major centers of the plastics industry to offer you the fast service you need . . . when and where you need it. Remember you can count on Koppers.

KOPPERS

SUPER DYLAN® THE POLYETHYLENE WITH MUSCLES

Here's a new polyethylene that loves tough assignments. If you need a plastic that must resist chemicals; have tensile strength; remain tough at low or high temperatures; color easily and yet have a glossy finish and be easy to process . . . choose SUPER DYLAN polyethylene. Here's why . . .

TENSILE STRENGTH. Pipe made from SUPER DYLAN has three times the short-term burst strength of conventional low density polyethylene. 1-inch IPS Schedule 80 pipe made of SUPER DYLAN has tested over 1,000 psi gauge pressure before bursting (at room temperature). A like pipe of conventional polyethylene burst at 350 psi.

CHEMICAL RESISTANCE. Because SUPER DYLAN is an ethylene polymer, it is not attacked by acids (including hydrofluoric acid which dissolves glass) or alkalies.

APPEARANCE AND COLORING. Unlike lower density polyethylene, SUPER DYLAN products have a smooth, glossy appearance. SUPER DYLAN is transparent in very thin sections and has a milky-white, translucent appearance in thicker sections. These factors make a wide range of colors possible.

EASE OF PROCESSING. In spite of toughness, improved heat resistance and rigidity, SUPER DYLAN is remarkably easy to process. In conventional molding machines it molds within the normal range of molding temperatures. It usually requires 50° F. higher cylinder temperature than low density polyethylene and 30° to 50° F. less heat than many impact-type polystyrenes.

HIGH TEMPERATURE TOUGHNESS. At 15 psi steam pressure, SUPER DYLAN samples suffered maximum observable dimensional reduction of only 4%, while conventional polyethylene became a shapeless mass.

LOW TEMPERATURE TOUGHNESS. In comparative tests, SUPER DYLAN bars chilled to −100° F. remained intact when subjected to 32 foot-pound per inch of face blow in an Izod Impact machine. Low density polyethylene snapped.

ENVIRONMENTAL CRACK RESISTANCE. Specimens of low density polyethylene and SUPER DYLAN polyethylene bent to U shape were immersed in an active detergent. Exposure continued for three months. Before the end of this time, all the lower density polyethylene specimens broke, while the SUPER DYLAN remained intact.

MANY APPLICATIONS. Versatile SUPER DYLAN polyethylene is superior for use in the manufacture of toys, kitchenware, auto parts, pipes and fittings, bottles and carboys, packaging films, washing machine agitators, refrigerator parts, battery cases and thousands of other products where strength, improved heat resistance, rigidity, impact and chemical resistance are important.

TYPICAL PHYSICAL PROPERTIES OF SUPER DYLAN POLYETHYLENE

PROPERTY	UNITS	TEST METHOD	RANGE OF VALUES
PHYSICAL AND MECHANICAL			
Density		ASTM-792-50	0.95-0.97

§Black only, for potable water piping.

DYLITE® EXPANDABLE POLYSTYRENE

This puffable plastic is practical, versatile and strong

DYLITE expandable polystyrene is proving itself as one of the most versatile foam plastics. New uses are constantly being discovered. Product performance has been demonstrated in uses for component parts of refrigerators, buoyancy applications, index packaging, structural panels for housing, pipe insulation, cold storage insulation, toys and display items. Although it's light in weight, its resistance to impact is amazing. Insulation qualities are high while water absorption and vapor transmission are low.

LIGHT YET STRONG. Once DYLITE granules have been expanded in a mold, they form extremely light, yet strong, rigid molded shapes.

IT FLOATS. Because DYLITE plastic floats, it is ideal for making floats, boats, toys and buoys. One cubic foot of DYLITE in a 2 lb./cu. ft. density will easily support 60 pounds in water.

LOW THERMAL CONDUCTIVITY. At 2 lb./cu. ft. density, this foamed plastic has a K factor of 0.22 at 70° F. mean temperature.

WATER ABSORPTION AND VAPOR TRANSMISSION—both low. Since DYLITE plastic has microscopic cells, individual closed cells of the polystyrene keep the water absorption rate low, in fact, less than 0.5% by volume for a 2 lb./cu. ft. density sample. Vapor transmission is only 0.5 to 1.0 grains/hr./sq. ft./inch of thickness/in. Hg. vapor pressure differential.

EASY PROCESSING. DYLITE expandable polystyrene beads can be molded and extended into nearly any shape or form. Subject to heat and pressure, these beads will expand to fill the entire mold cavity. Density is varied by controlling the amount of beads used.

Dylite for slab insulation! Extruded in boards, it can be sawed, drilled, plastered or painted, and cut to specifications with a hot wire. A board foot weighs just 1.3 ounces. Low K factor and good moisture resistance mean excellent insulation.

Fragile items get an easy ride to their destinations when they're packed in Dylite. In addition, the Dylite package makes an attractive point-of-purchase display.

Here's another example of how the low K factor of Dylite really pays off. Ice cubes last longer in this one-piece, seamless Dylite ice bucket that won't sweat or scratch furniture. It's lightweight, practical and durable.

DYLAN® POLYETHYLENES

DYLAN polyethylene is soft and flexible, ideal for squeeze bottles, film and packaging.

DYLAN 3500—Ideal for sheet extrusion and bottle blowing.

DYLAN 3555—Excellent for film blowing.

DYLAN 3700—General purpose and injection molding. Melt index 2.5 plus or minus .5.

DYLAN 3900—Injection molding grade with a melt index of 9 plus or minus 1.0.

DYLAN 4200—Easier flow injection molding. Melt index 17.5 plus or minus 2.5.

DYLAN 4400—Still easier flow with melt index of 22.5 plus or minus 2.5.

Pipe Polyethylenes

DYLAN polyethylene 3000—For potable water.* Only carbon black added.

DYLAN polyethylene 3016—Carb[illegible] black and antioxidant added.*

DYLAN polyethylene 3028—Carb[illegible] black and antioxidant added.*

(Note: Carbon black and antioxidants varied according to customer's reque[illegible])

**National Sanitary Foundation Testing Laboratory at the School of Public Health, University of Michigan, has tested and approved these three* DYLAN *polyethylenes as suitable for conveying potable water supply.*

DYLENE® POLYSTYRENES

DYLENE polystyrene is a rigid thermoplastic readily formed by ordinary methods such as injection molding, extrusion, compression molding, vacuum forming, etc.

Normal DYLENE Polystyrenes

TYPE 2—Ease of molding makes it ideal for use with large and/or small, intricate mold designs.

TYPE 3—Fine molding characteristics make it good for general uses where moderate heat resistance is necessary.

TYPE 4—Use where easy flow and fast setup are of critical importance.

TYPE 7—Excellent general purpose polystyrene with a typical heat distortion temperature of 194° F.†

TYPE 8—Typical heat distortion temperature of 201° F.† is combined with excellent electrical and mechanical properties.

Medium impact DYLENE Polystyrenes

TYPE 30—For appliance parts. Has easy molding characteristics and typical heat distortion temperature of 175° F.†

TYPE 80—Has excellent typical heat distortion temperature of 195° F.†

High impact DYLENE Polystyrenes

TYPE 200—Easy molding and impact resistance make it ideal for large parts such as refrigerator inner door liners, appliance housings, etc.

TYPE 201—Especially designed for sheet extrusions where high luster without overlay is desired.

TYPE 305—For general purposes. Typical heat distortion temperature of 175° F.† and easy moldability are special features.

TYPE 708—Intended for electrical use. Low water absorption for high impact type. Typically medium heat resistance.

TYPE 800—Typical heat distortion temperature of 195° F.† and ready moldability are outstanding features of this polystyrene.

FIBERTUFF® polystyrene (Glass Fiber Reinforced)—For injection molding of strong rigid parts where resistance to distortion by heat or to cold flow are essential. Resists shattering at both ordinary and sub-zero temperatures.

†*ASTM D648*

Fully detailed and illustrated technical folders are available on DYLAN, SUPER DYLAN, DYLITE, *and* DYLENE *plastic materials. They're yours for the asking. If yours is an unusual problem, our staff of technical men are ready to give their help in solving your problems. A call, wire or letter to any of the Koppers sales offices listed below will bring technical information or assistance . . . right to your plant. Count on Koppers.*

BARRON PLASTICS

Plastic Sign Letters For Top Visability Signs

A
B
C

The design and brilliance of Barron Plastic Sign Letters make attention compelling, easy-to-read signs. Embossed, rounded letters. Permanent, clean and easy to clean. Use indoors—in windows, shops, offices, factories. Easy to apply and cost less than hand-lettered signs. 1", 1½", 2", 3" and 4"—choice of standard colors. Write for details.

Fabrication -- Molding

Any item fabricated in plastics to your specifications. Custom extrusions. Injection molding of advertising novelties, insignia, plastic parts. Large or small runs at lowest prices.

We can supply your needs, for practically any plastic you want, from one of the most complete stocks in the country. Mill shipments and special orders quoted on request. Butyrate and high impact Styrene sheets for vacuum forming.

ACETATE	SARAN
ACRYLITE EMBEDDED	PHENOLIC
BUTYRATE	POLYETHYLENE
MYLAR	P. V. C.
NYLON	TENITE II
PLEXIGLAS	VINYLITE
POLYSTYRENE	TYGON

Butyrate Tool Handle Stock For Prompt Shipment

Order Eastman Butyrate (Tenite II) round tool handle stock direct from this size and color chart — world's largest stock of assorted sizes and colors. In stock for prompt shipment. 72" lengths.

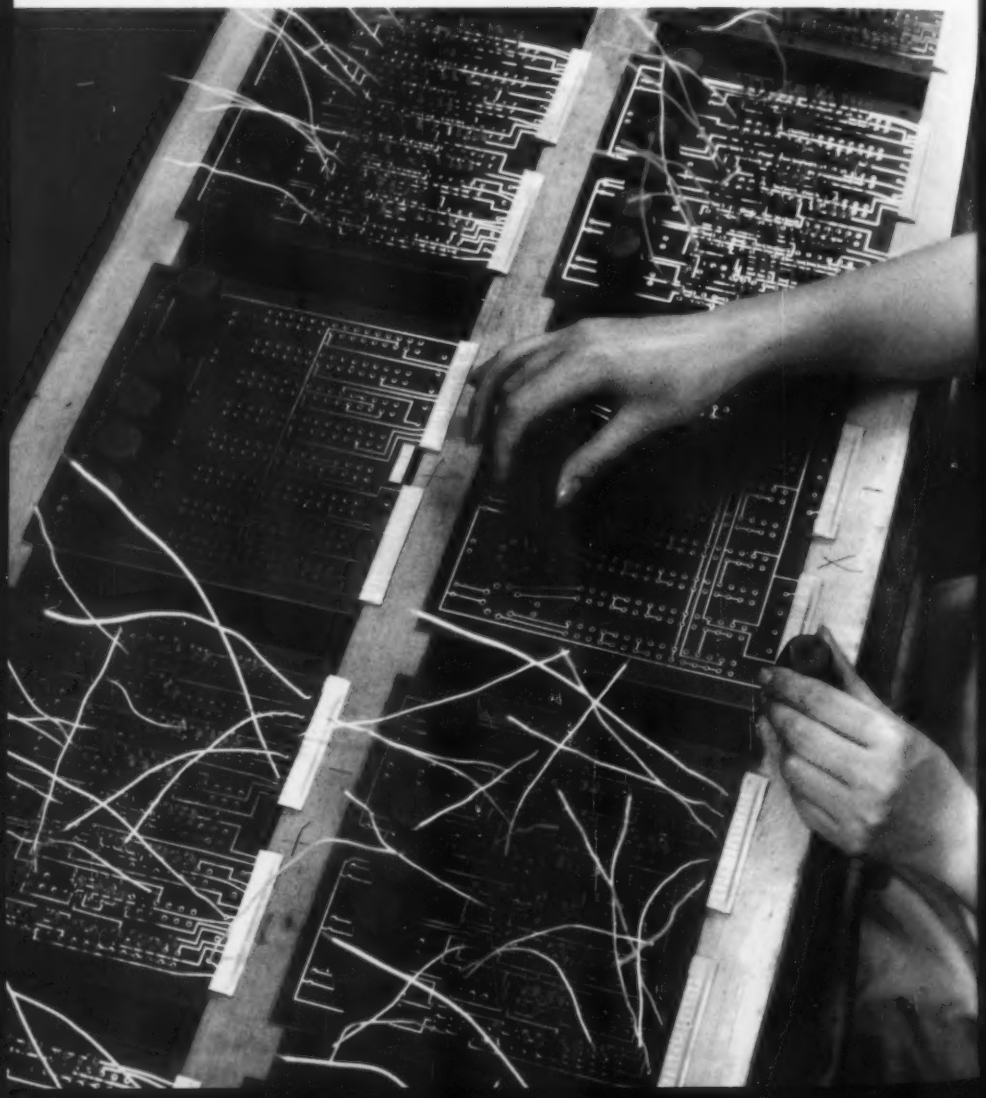
*** A WORD ABOUT PLASTICS**



Each plastic group is **defined** by a chemical formula and should be **confined** to evaluated areas of application. Properly evaluated, plastics serve an essential role both as primary and as complementary raw materials. This proper evaluation demands the co-operation of the raw materials' supplier, the fabricator, the designer and the engineer.

PHENOLICS

THE PIONEER PLASTIC

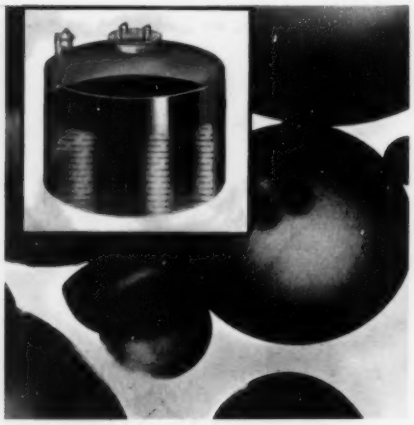
The plastic industry, as it is known today, began at the turn of the century with the development and almost immediate commercial use of BAKELITE phenolic plastics. The use of phenolic materials expanded as other industries such as radio and transportation grew during the first half of the twentieth century. In this continuing path of progress, phenolics served as the catalyst for some of these industries so that today it might be said that phenolics are essential to our national economy. The phenolic resins marketed by Bakelite Company are generally classified as molding materials, bonding and laminating resins, and coating resins. Over the years, general-purpose phenolics satisfying a wide variety of uses have been developed. However, as is true of all plastic materials, phenolics can be formulated to meet specific requirements.

Essential to the success of the printed circuit was the development of insulating base materials with the proper electrical properties. Bakelite Company was instrumental in providing a phenolic laminating resin that met critical specifications — this material is now accepted as standard throughout the industry.

in particular, phenolics offer...

molding

STRENGTH — Phenolics harden into an infusible state. Many applications of phenolic, such as this washing machine agitator, evidence remarkable impact, tensile and flexural strengths — rigidity and dimensional stability.



coatings

DURABILITY — Important in all applications, phenolics not only protect but also endure. For sixteen years, phenolic based coatings have protected this bridge.

bonding

HEAT RESISTANCE — Phenolics are available that will withstand temperatures as high as 400 deg. F. for long periods of time, even as much as 500 deg. F. for shorter periods. Heat stability is an all important property in phenolic-bonded abrasive grinding wheels.

evaporation control

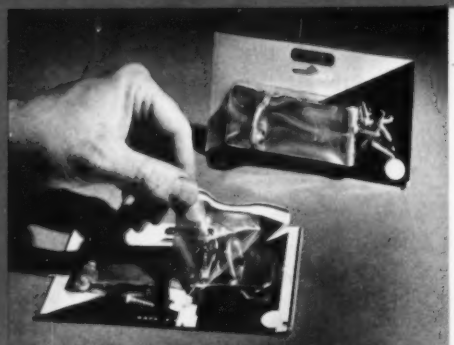
VERSATILITY — Millions of microscopic hollow phenolic spheres serve as a floating blanket to cut evaporation losses in crude oil storage tanks.

Copyright 1957 by UNION CARBIDE CORPORATION.
The terms BAKELITE, KRENE, and UNION CARBIDE are registered trade-marks of UCC.

VINYLS

VERSATILE VINYLS

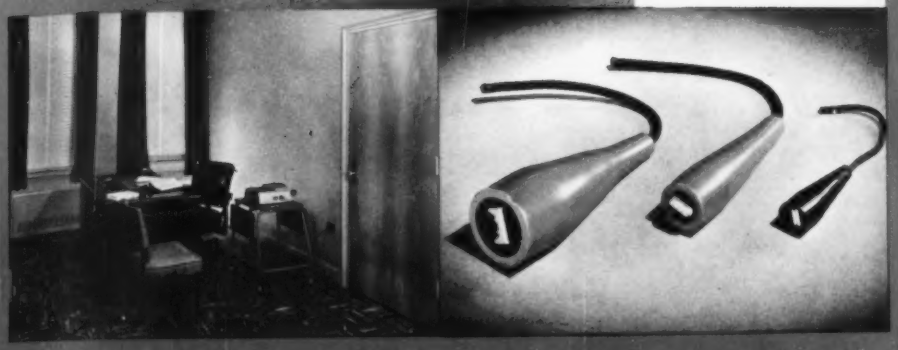
First produced on a commercial scale by Carbide and Carbon Chemicals Corporation, another division of Union Carbide Corporation, vinyls today perform vital services in almost every branch of industry and home life. The ever increasing application of BAKELITE vinyls has been paced by the development of newer and improved vinyl resins and compounds. These developments improved established applications and made possible others which before may only have existed on the designer's drafting board. Bakelite Company produces the world's largest variety of vinyl raw materials. For this reason, we can supply vinyl materials to conform to almost any requirement and to meet successfully a wide range of demanding specifications.



Vinyl gives an application the "handmade" look plus ruggedness and long service life. Extruded luggage bindings give that type of service — toughness and abrasion resistance. Calendered vinyl is also used extensively for luggage covering.

cases in point...

skin packaging



STRENGTH AND CLARITY — KRENE cast vinyl film is indispensable for the new skin packaging technique — crystal clear film is vacuum formed around saleable items securing them to appropriate merchandising cards.

vacuum forming

COLORFUL AND PRINTABLE — Rigid vinyl sheets can be pigmented in a wide variety of colors and multicolor printed to provide attractive designs and patterns.

calendering

PARTICULARLY VERSATILE — Rigid or flexible, transparent or opaque, whatever the application requires. The walls, floor and upholstery in this office are covered by appropriate types of calendered vinyl.

molding

ELECTRIC RESISTANCE — Remarkable insulating properties plus greater durability make electric insulation practical — as evidenced by the vinyl insulation on these terminal clips. Vinyl withstands abrasion and rough handling and can be formulated to give exceptionally high flexibility.

coatings

CHEMICAL, WATER AND ABRASION RESISTANCE — Vinyls are compounded for extreme chemical inertness, and for resistance to water and abrasion. An extremely fast drying, easily applied vinyl resin paint system has given effective protection against corrosion and abrasion on these Mississippi dam gates for eight years.

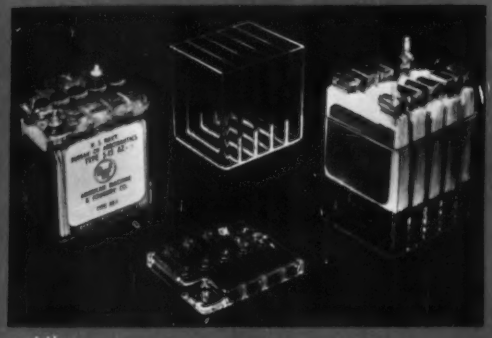
STYRENE

THE STYRENE STORY—
DEPENDABLE and FUNCTIONAL

In the quarter century that styrene has been on the commercial scene it has become recognized as one of industry's most versatile plastics. Styrene can be found in applications ranging from toys to battery cases and from brushes to refrigerator door liners. This is quite plausible since modifications in the basic styrene resin and its copolymers have resulted in compounds that offer varying degrees of impact, heat and chemical resistance. Modifications offer a wide range of properties and colors to meet the growing demands of an ever-broadening consumer market — demands which translate as a variety of product specifications that BAKELITE styrene helps you to satisfy. These compounds are available in an almost unlimited range of colors which may be transparent, translucent or opaque.

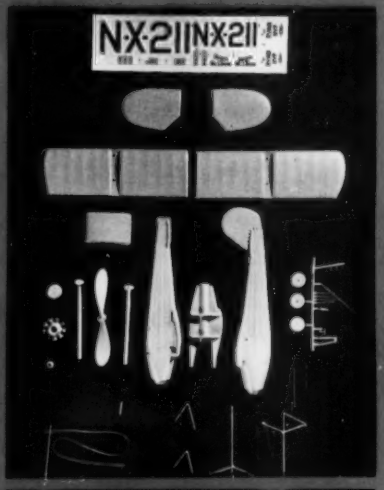
Styrene offers beauty. Color, gloss and smooth finish are features of these styrene flower pots. These are properties common to styrene compounds. Pigment dispersion is so thorough, color is an integral part of the finished product.

styrenes have much to offer... for example...



extrusion

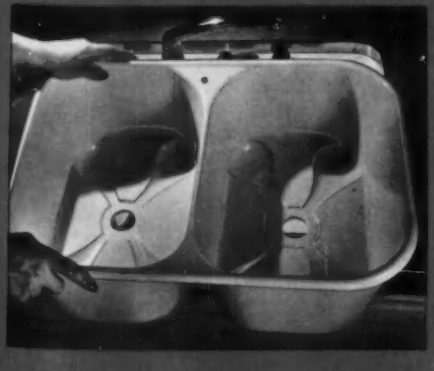
VERSATILITY AND DURABILITY — Long lasting brush bristles — extruded styrene monofilaments.



extrusion

IMPACT RESISTANCE — Strength, even in thin sections, afforded by BAKELITE Brand impact styrene makes these dishes and trays a useful addition to the modern kitchen. Note superior gloss!

molding

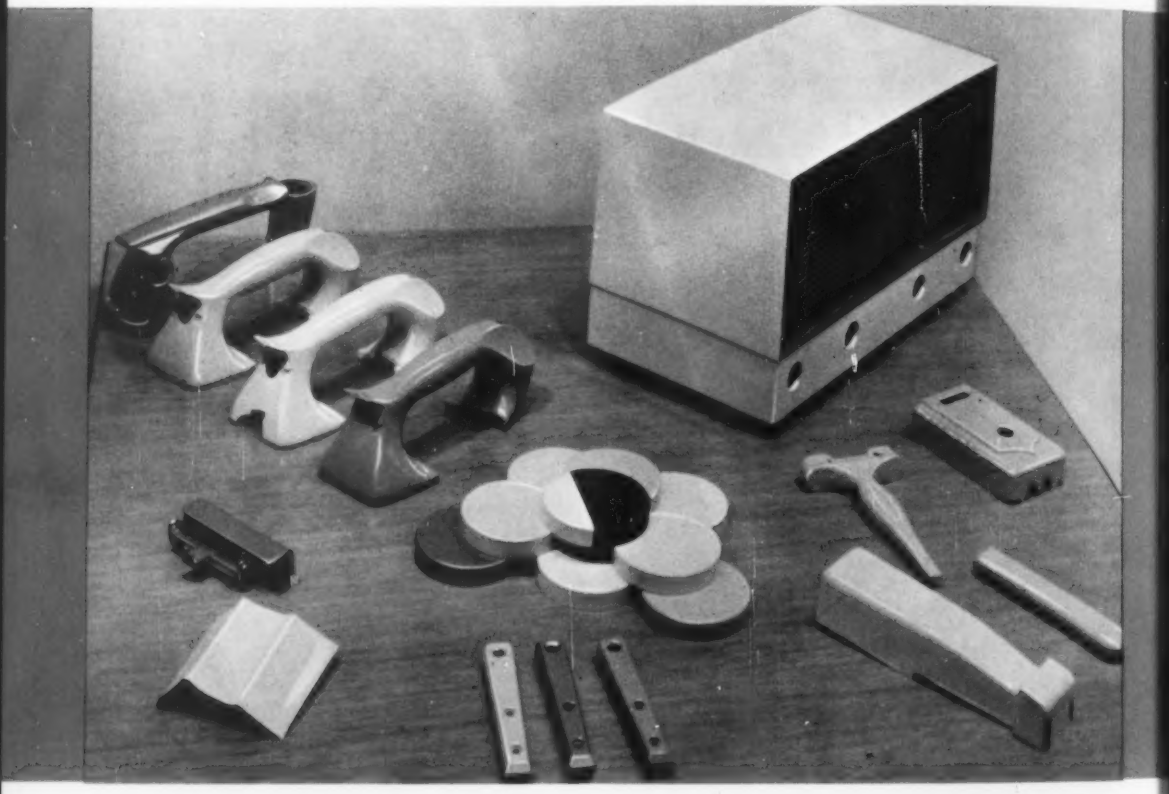


CHEMICAL RESISTANCE — Styrene products withstand the attack of salts, acids and alkalies. For more demanding applications, a styrene copolymer material, C-11, was developed to offer additional resistance to soaps, detergents, fats, kerosene, various solvents, oils and even battery acids.

vacuum forming

FORMABILITY — Ease of formability ensures uniform production rates essential to mass production assembly lines. This intricate toy plane, vacuum formed from extruded styrene sheet, indicates the facility with which the material forms.

extrusion



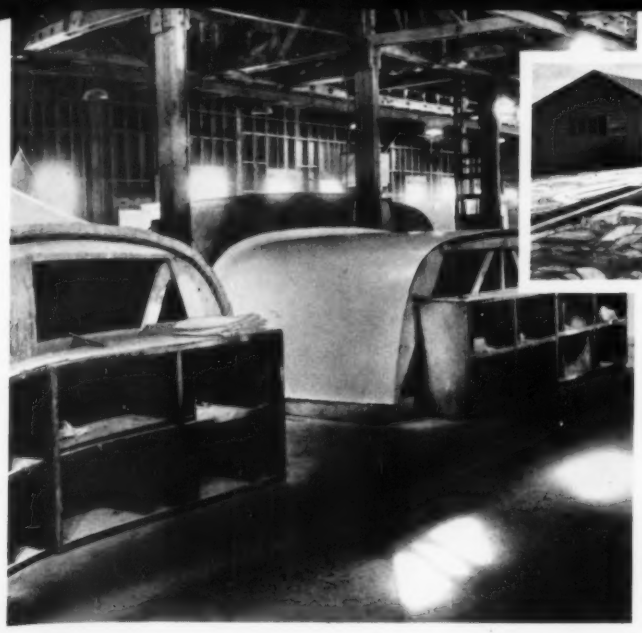
HEAT RESISTANCE — For applications requiring a high heat resistance, Bakelite Company offers a specially formulated styrene with an ASTM rating of 197 degrees Fahrenheit. Dual sinks fabricated from extruded styrene sheet have been very successful in resisting the effects of hot dish water.

EPOXIES

IN TEN SHORT YEARS...

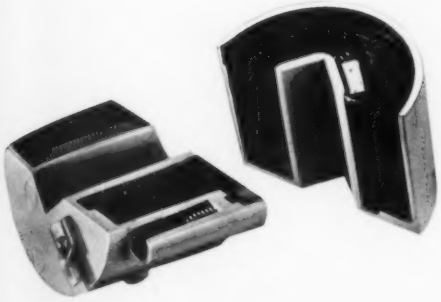
Epoxy resins have exhibited one of the most impressive growth patterns of any newly developed plastic. An excellent combination of outstanding properties accounts for their quick acceptance and wide range of uses. In applications such as: surface coatings, potting and encapsulating of electronic and electric assemblies, tooling compounds, plastic laminates and adhesives, the outstanding properties of epoxies are dramatically demonstrated. For instance, in tooling, epoxies have resulted in substantial time, labor and money economies. As a basic raw materials supplier, Bakelite Company markets epoxy resins to a broad segement of industry.

epoxy resins exhibit



A coating based on BAKELITE epoxy resins — color now where there was no color.

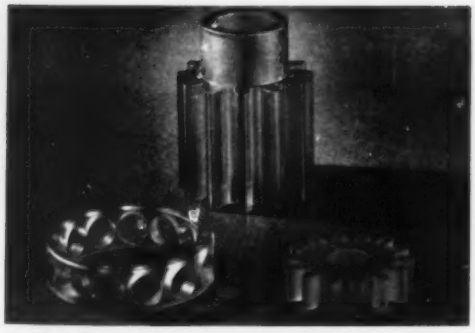
bonding



ADHESION — Ability of epoxies to bond such products as ceramics, glass, aluminum, ferrous metals, wood, most plastics and rubber, enhances the serviceability of these materials in many fields.

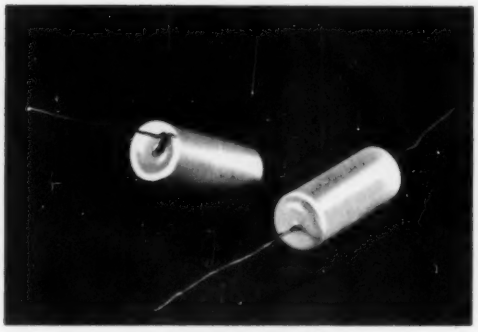
bonding

VERSATILITY — The various sections of the pool are formed from these giant molds made with a compound based on epoxy. This glass fiber-reinforced plastic swimming pool presents a relaxing scene that belies the careful, detailed design involved in its production.



potting

ELECTRICAL PROPERTIES — This coil demonstrates superior dielectric strength. Working life is extended and efficiency is improved when assemblies are protected by epoxy resin.



body solders

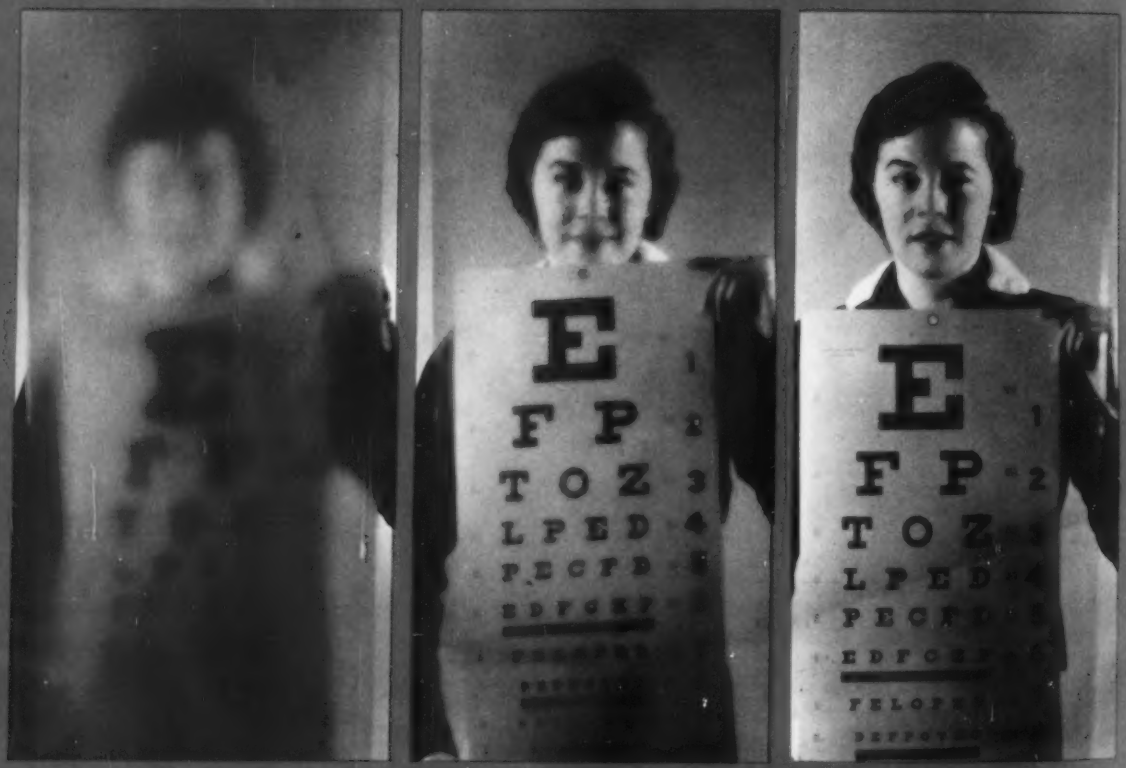
CURING ADVANTAGES — Cured at room temperature glass cloth-epoxy fender patch reduces cost 70 per cent.

casting

DIMENSIONAL STABILITY — Not only do premium parts cast from epoxies ensure close tolerances in reproduction but also maintain this accuracy throughout the life of the component.

encapsulating

CHEMICAL, MOISTURE AND FUNGUS RESISTANCE — Epoxies resist corrosion, most chemicals, fungus and moisture penetration. Electronic capacitors encapsulated in epoxy are assured substantial increase in service life.



POLYETHYLENE

A NEW LOOK AT POLYETHYLENE

First in production, first in quality and first in performance summarizes the role of BAKELITE polyethylene in the plastics world. As early as 1943, when polyethylene was first used as high frequency insulation on Navy radar, Bakelite Company was a pioneer in the development of this history making material. Today, our laboratories are not only actively engaged in maintaining and improving the qualities of our resins but are also discovering new and better production techniques which will expand the fields of application for this key plastic material.

Design engineers, the world over, have found polyethylene an invaluable and essential item for these reasons . . .

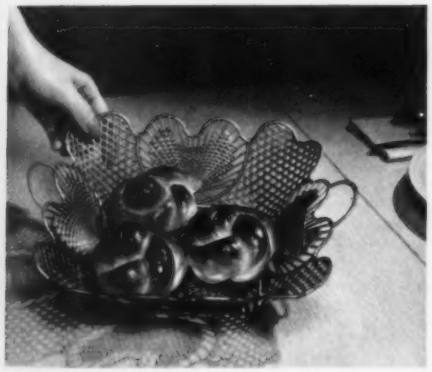
These photographs dramatically illustrate the progress made in developing excellent optical properties in polyethylene film. Through the constant effort of research and development, Bakelite Company continues to offer film extruders a wide range of polyethylene resins and compounds. The films made from these compounds can be used, creatively, to satisfy a variety of packaging requirements, thereby helping users to increase sales.

molding

FLEXIBILITY—Polyethylene is flexible without plasticizers, case in point, molded squeeze bottle. This plastic will retain inherent flexibility over a wide temperature range.

extrusion

ELECTRIC RESISTANCE — Superior low-loss electrical properties of polyethylene recommended it for the major insulation material on this — the first transatlantic telephone cable.



calendering

MOISTURE RESISTANCE — This calendered, embossed tablecloth is tough and flexible, and resistant to most household fluids. It stands up under daily multiple washings. Color is an integral part of the finished product — it can not scratch or wash off.

packaging

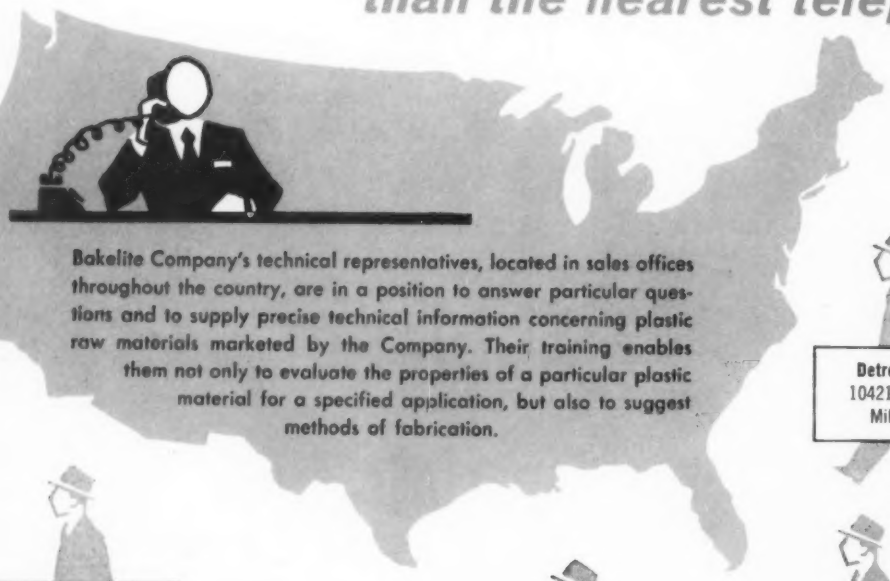
VERSATILITY — Polyethylene has high tear strength, extremely low moisture-vapor transmission, is odorless and tasteless. Its permeability for both oxygen and carbon dioxide permits perishables to **breathe,** thus prolonging their preservation. This is evidenced by the wide acceptance of polyethylene packaged foodstuff.

molding

FORMABILITY — A free flowing thermoplastic, polyethylene can be formed in myriad shapes and sizes. One example — this intricately designed basket was injection molded.

extrusion coating

CHEMICAL RESISTANCE — Polyethylene coats the inner surface of this package. The chemical inertness of polyethylene is utilized here to preserve the high purity of research grade chemicals.



extrusion

LIGHT WEIGHT — Weighing less than water, polyethylene has the lowest specific gravity of any commercial plastic. Greater yield per pound results in reduced costs for manufacturers of polyethylene products.

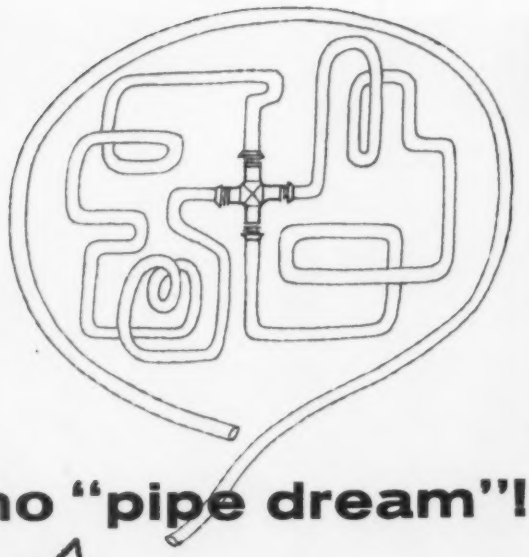
PROFITS UP! **COSTS DOWN!**

when you use

MUEHLSTEIN *reprocessed plastics*



Big material savings plus top quality and efficient color matches add up to increased profits. And that's what you get when you use Muehlstein reprocessed plastics. You're assured of satisfaction when Muehlstein technicians go to work on your special plastics problem. Call on Muehlstein and watch your profits go up.

Muehlstein offers top prices for distressed inventories of molded parts, purgings, and all thermoplastic materials.

no "pipe dream"!

No **"maybes"** about it! Whether it's polyethylene pipe or packaging or pails you're producing or planning, chances are Interplastics can save you money with carefully processed polyethylene, natural or colored. Sometimes we have attractive spot lots of virgin polyethylene, too.

But that's not all—Interplastics also deals in polystyrene, nylon, acrylics, vinyl and cellulosics. And —if you have scrap or surplus materials for disposal, we would like to buy it.

Exporters and foreign customers can depend on Interplastics' experienced export and import department. Ask for our handy materials reference index.

INTERPLASTICS CORPORATION

GERALD F. BAMBERGER, president

120 East 56th St., New York 22, N. Y., U. S. A.

OUR ONLY FUNCTION IS TO SAVE YOU MONEY

Don't sell that scrap!

Those piles of thermoplastic scrap can easily be converted into high quality materials by our reprocessing methods. Just ship them to ERIE PLASTICS. We're set up to handle every step in every reclaiming operation. We will clean and pelletize your scrap and return it to you as good as new. And we can change the color of scrap, too.

We reclaim

- **polystyrene**
- **acetate**
- **butyrate**
- **polyethylene**
- **nylon**
- **vinyl**

Next time you have scrap of any of these thermoplastics, get in touch with ERIE and find out how inexpensive it will be to convert this overage into re-usable material.

polyvinyl materials

● In little more than a decade, polyvinyl materials —of which Geon is recognized as a standard of excellence—have zoomed to high prominence in plastics. It is estimated that vinyls will become the first plastic to reach a billion-pound-a-year production figure.

ADVANTAGES

The popularity of Geon materials results from an excellent combination of properties—inertness or resistance to attack, superior electrical properties, adaptability of physical properties to meet a wide range of requirements. With proper selection of compounding ingredients, vinyl products can be made which resist most acids, alkalis, alcohols, oils and solvents—and possess exceptional abrasion and weather resistance.

VERSATILITY

End products made from Geon resins or plastics range from flexible upholstery to rigid pipe. Geon may be expanded into foam products like cushioning. Or Geon in liquid form can be applied as a coating to other materials such as paper or fabrics. End products can be made transparent, opaque or translucent in brilliant or subdued colors.

PROCESSING

Processors find Geon a highly uniform, and highly versatile material with which to work. It can be extruded, injection or compression molded, cast, expanded, calendered, used for coatings . . . depending on requirements of the application.

SERVICE

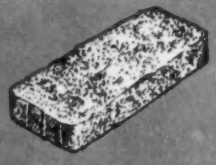
B. F. Goodrich Chemical Company's experience with Geon dates from 1939, when scientists in our laboratories first learned how to make polyvinyl chloride into a useful, workable plastic. Thus our organization, and Technical Development Laboratory, is uniquely equipped to help you apply Geon raw materials for new and better products.

the four basic forms of Geon materials

resins

are free-flowing white powders generally requiring compounding with other ingredients to produce plastics.

plastics



are resins compounded at our plants ready for extrusion or molding. A large number of compounds in cubical form are available in a wide range of colors especially formulated and tested for specific uses.

latices

are water dispersions of polyvinyl chloride polymers supplied as stable, milk-white liquids of approximately 50% total solids. They form clear, tough films or coatings and can be compounded to give opaque or colored deposits.

polyblends

are resins plasticized with Hycar nitrile rubber, supplied in sheets similar in appearance to crude rubber. Nitrile rubber plasticizer provides the advantage of non-extractability for such applications as food packaging and cable jacketing.

Wall Covering made of Rigid Geon provides realistic effect of brick or stone, is waterproof, washable, resists oil and grease.

Wall Covering with Geon Coating has a fabric base material. It is produced in a range of colors from pastels to deep tones, is attractive and durable.

Geon
Polyvinyl Materials

Calendering & Coating

Products range from flexible upholstery to rigid panels; decorative to functional coatings

Rigid Vinyl Windows are installed easily—simply nailed in place. They resist corrosive atmospheres as well as weather.

Convertible tops coated with Geon are available in a wide range of fade-resistant colors. With the fabric protected, tops last longer in weather.

Geon-Coated Nylon proves a superior material for these two applications: swimming pool and tarpaulins. This construction is light yet strong, waterproof, resistant to wear and tear.

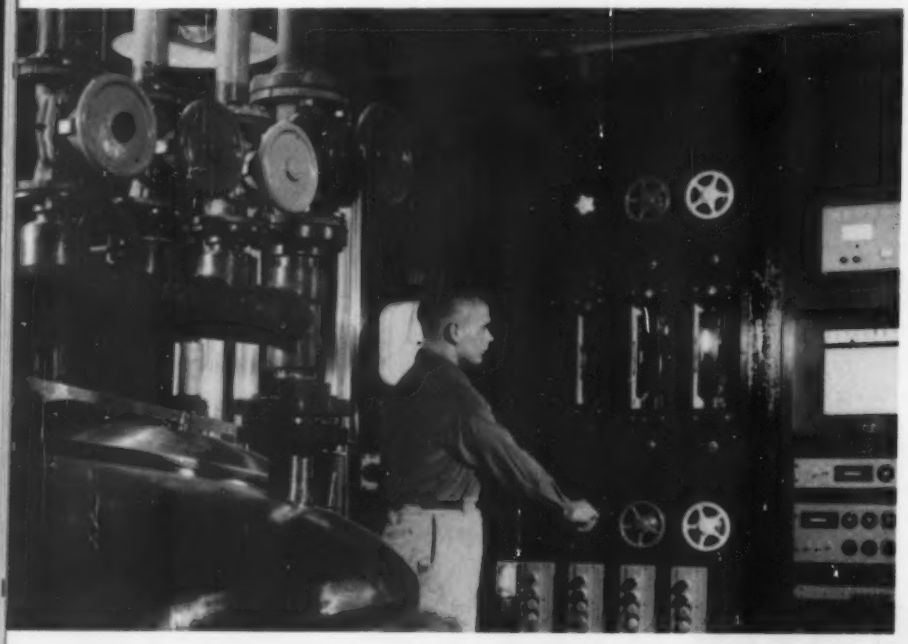
● Calendered film materials made from Geon are familiar as shower curtains, bedspreads, bowl covers, raincoats, protective covers, and many others. Heavier sheeting is used for upholstery, tarpaulins, luggage. Geon may be supported by a backing material for added strength.

Geon latex is an ideal lightweight coating. Paper may be coated for decorative reasons, as in wallpaper or shelfpaper, or for functional reasons, as in food packaging papers. Coatings may be applied to fibers to provide exceptional resistance to oil, chemicals, and water.

Coating Materials include Geon latices, preferred where thin pin-hole free coatings are desired without requiring use of volatile solvents; Geon resins for plastisols and organosols, preferred for medium and heavy coatings; solvent solution systems, most useful for thin coatings, particularly where very high gloss or transparency are desired.

Another application is the use of Geon for pigment and fiber binding and paper saturation. For example, Geon latices make a continuous sheet of random or oriented fibers in making non-woven fabric.

Vinyl coating on Steel provides a tough, handsome finish for business machines. The same coating on metal drums or tanks can provide resistance to chemical attack.



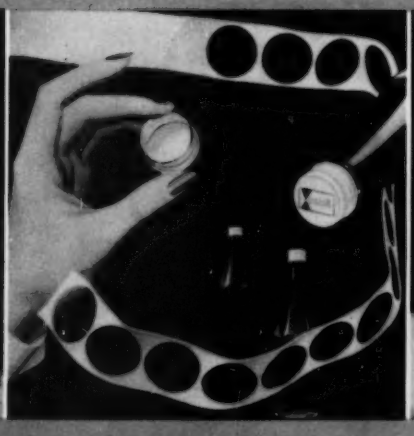
B.F.Goodrich Chemical Company

Extrusions

From superior electrical insulation to gasketing; flexible belting to rigid pipe and ducts

● Geon polyvinyl materials offer outstanding ease of processing by extrusion. The product range is extremely wide. Some examples are thin and heavy walled tubing and hose, belting, trim for luggage and upholstery, gasketing, electrical tape, rigid corrosion-resistant piping and ductwork.

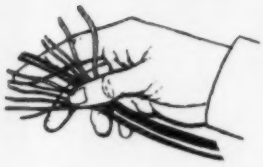
Geon is also extruded as a covering on other materials—as a weather resistant coat on clothes lines, as sturdy insulation on wire and cable, and lightweight cable jacketing.

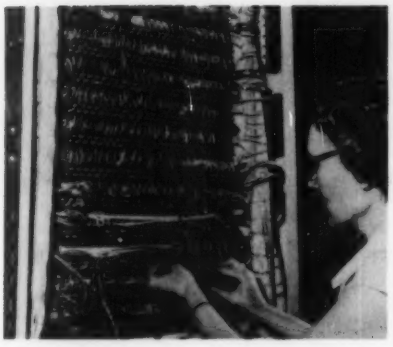


Rigid Vinyl is a fast-growing material for piping that must withstand chemical attack. It is also immune to galvanic corrosion, eliminating the major source of failure in underground lines. Vinyl pipe is light weight, easy to install.

Plastic Springs—special jacketing compound extruded on telephone conductors provides unique flexing action.

Weather Stripping molds itself perfectly to irregularities or gaps in windows or doors, withstands rough weather.





Bottle Cap Liner is white, clean-looking, exceptionally smooth. Eliminates sticky caps, provides excellent seal.

Drain Rail keeps water out of convertibles. Geon is ideal here because it won't crack, chip or peel.

INSULATION

Electrical panel in aircraft uses color-coded wiring with insulation of Geon.

Building wire insulated with Geon materials has exceptional aging characteristics, maintains insulation strength and flexibility.

● Geon vinyl compounds and resins for primary insulation and jacketing have extended their usefulness many times since their introduction twenty years ago. Applications include building wire, communications and electronics wiring, automotive secondary wiring and electrical equipment.

This insulation offers outstanding advantages: excellent dielectric properties combined with good resistance to abrasion, weathering, and heat; nonflammability, low temperature flexibility, and extreme inertness to oil, chemicals, and solvents. In addition, Geon vinyl retains its properties over many years of severe use, indoors or out.

Geon electrical-grade materials are supplied either as finely powdered resins, or as completely compounded plastic cubes of uniform size. The resin permits the processor to select modifying ingredients and compound to his own specifications. Geon plastic compounds are generally used as supplied and are available in different formulations designed to meet many government and underwriters standards.

B.F.Goodrich Chemical Company

Molding

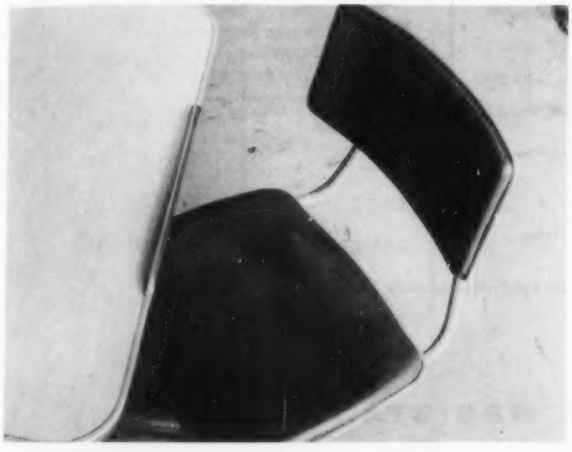
For rigid phonograph records and soft dolls, and a new star—vinyl foam

Rotational Casting of toys is handled by this automatic machinery. Molds which are carried on chain pass through the oven to fuse the Geon plastisol.

Rigid vinyl moldings include automobile dashboard, piping tee, motor housing.

● The versatility of Geon polyvinyl materials is shown by the many types of products which can be made by molding processes. High fidelity phonograph records are compression molded, pipe fittings injection molded. Slush- or low-pressure molding of Geon plastisols is used for dolls, toys, fish lures and gaskets.

Foam products made of Geon are proving superior in cushioning material, floats, shock-absorbing padding in automobiles, thermal insulation, etc. Either open or closed cell vinyl can be produced from Geon paste resin.



Modern Packaging of Geon helps sell the merchandise. Other packaging uses for Geon include protective paper coatings, film, sealants, tape, barriers.

Drain Rail for carrying water from freezing unit is one of the largest injection molded vinyl parts ever made. Easy to clean, stays flexible, odor-free.

High Fidelity Records are pressed from Geon resin. Uniformity, wear resistance, and dimensional stability are highly important.

School Can Be Fun. Cushioning material of Geon foam makes comfortable seating that keeps its spring and resiliency.

Foam and Sponge

• Expanded vinyls have opened many new-product markets. The closed cell vinyl structure is referred to as "sponge", the open cell structure as "foam". Foam (or sponge) is excellent for insulation, shock absorbing, and cushioning applications. In addition sponge is used for buoyancy.

To make vinyl sponge, a chemical blowing agent is incorporated into a plastisol and fusing is done under high pressure in a mold. The blowing agent decomposes under the heat to liberate a gas (usually nitrogen) which expands the vinyl.

Foam is made by dissolving an inert gas in a plastisol under relatively high pressure and releasing it through a spray nozzle into a mold or onto a casting surface. Fusion is then done by dielectric heat. By the use of this patented method, continuous production of vinyl foam is commercially successful.

It Floats. Swimming boards, fishing floats, boat bumpers all capitalize on buoyancy of Geon sponge.

Thirsty Mop has sponge-like strings made of Geon plastisol. The strings absorb more water, shed no lint.

B.F.Goodrich Chemical Company

TYPICAL PHYSICAL PROPERTIES

	Flexible Geon	Rigid Geon
Specific gravity	1.20-1.55	1.32-1.40
Ultimate Tensile Strength (psi, max.)	3,500	8,000
Ultimate Tensile Strength (psi, ave.)	1,500-3,500	5,500-7,000
Ultimate Elongation (%)	200-450	5-25
Hardness (Shore Durometer A)	50-100	70D-85D
Maximum Service Temperature (°F)	170-220*	150
Minimum Flexibility Temperature (°F)	0 to -70	—
Abrasion Resistance	excellent	excellent
Age Resistance	excellent	excellent
Sunlight Resistance	excellent	excellent
Electrical Properties Volume Resistivity (ohm-cm at 25 °C) (maximum)	$1\text{-}10 \times 10^{12}$ to $4\text{-}7 \times 10^{14}$	$1\text{-}5 \times 10^{14}$ to $1\text{-}5 \times 10^{16}$
Dielectric Constant at 60 cycles at 25 °C	5.5-9.1	2.3-3.7
Power factor at 60 cycles at 25 °C	0.05-0.15	0.02-0.03

*Underwriter Lab approval granted for electrical compound to be used continuously at 105 °C (220 °F)

TYPICAL CHEMICAL RESISTANCE DATA

Type of immersant	*Geon*
Acidic Salts	excellent resistance
Alcohols	resists action of aliphatic alcohols
Aldehydes	resists action of formaldehyde
Alkaline solutions	excellent resistance
Esters	not recommended because esters are softeners for polyvinyl chloride
Halogenated Hydrocarbons	not recommended
Inorganic Acids	resists most acids at all concentrations under a wide variety of conditions
Edible Oils	excellent resistance
Ketones	not recommended
Neutral Salts (Saturated Solution)	excellent resistance
Organic Acids	resists action of most acids, except glacial acetic.
Phenols	not recommended
Sulfur Derivatives	resists most aliphatic sulfur compounds except carbon bisulfide.
Vegetable Oils	excellent resistance
Water	excellent resistance

GUIDE TO GEON POLYVINYL MATERIALS

GEON MATERIALS	PROCESSING METHODS	FINISHED PRODUCTS
Polyvinyl Chloride Resins 101—General Purpose 101EP—Ideal for powder mixing 103EP—Lower temperature processing and rigids. 118—Easy processing calendering resin 202—General Purpose Copolymer	Calendering Press polishing Embossing Printing Spanishing Extrusion Injection molding Compression molding	Calendered Supported and unsupported sheeting for upholstery, luggage, wall covering, automobile interiors Films for shower curtains, rainwear, tablecloths, draperies Floor and wall tiles Extruded Wire and cable insulation Garden hose Tubing for beverage, industrial and pharmaceutical applications General extruded sections such as belting, welting, tapes, chair webbing and laces Injection molded Grommets, gaskets, electrical plugs, toys, automotive parts
Geon Polyblend 503 H A 45-55 colloidal blend of Hycar American rubber and Geon polyvinyl chloride in which the Hycar serves as a non-migrating plasticizer for the vinyl resin replacing the usual ester type plasticizers. Offers certain advantages of cementability and smoother extrusion.		
Geon Plastic Compounds A series of many different compounds in a full color range. For use primarily in wire and cable insulation, general extrusion, and injection molding. Supplied as cubical granules.		
Geon Resins *For Rigid Applications* 103 EP, 428, 404 HI, 421 — Special vinyl chloride polymers		Calendered Sheets for finishing by press polishing or laminating Extruded Wire and cable insulation Chemical piping, rod, sheets Compression molded Press polished and embossed sheets Phonograph records Injection molded Belt buckles Electrical parts Pipe fittings Phonograph records Deep drawn Chemical containers, fume ducts, hoods, etc.

Solution coating Roll coating Knife blade Air knife Dip Film coating Spray coating	Coated paper and fabrics Cast films Protective coatings on metals
Geon Paste Resins 121, 122 Vinyl chloride polymers of controlled particle size. Can be dispersed either in a resin-plasticizer-diluent system (organosol) or resin-plasticizer system (plastisol) to make a paste of spread or dip coating consistency.	Coating Knife Reverse roll Dip Spray Low pressure molding Casting	Spread coated Luggage and upholstery cloth, window shades, decorative paper Dip coated Gloves, wire dish drainers, electroplating racks, footwear Spray coated Wood articles, sheet metal Cast Film, toys, dolls, prosthetic devices Sponge and foam
Geon Latices 151, 450X167, 351, 352, 552, 576, 450X5, 652.	Coating	Coatings and binders for decorative paper, hot drink cups, food cartons, fiber, fabric, felt, leather

B.F.Goodrich Chemical Company

Other outstanding raw materials by B.F.Goodrich Chemical Company

Hycar

Hycar man-made dry rubbers are uncompounded polymers that include the oil resistant nitrile types, a polyacrylic for high temperature use, and a brominated butyl with exceptional characteristics of compatibility and cure. Compounding with vulcanizing agents, loading pigments and softeners is easily accomplished on conventional rubber equipment. Hycar rubbers are also supplied as water dispersions or latices that reflect the properties of their dry rubber component. Generally, Hycar materials are resistant to oil, solvents, and abrasion, have low compression set, and good aging qualities.

Good-rite CHEMICALS

Good-rite chemicals include antioxidants, hydrophilic polymers, biochemicals, and chemical intermediates. They have an outstanding reputation for purity and dependability. Experimental samples and further information are available on request.

Harmon COLORS

Harmon colors are organic pigments which offer a complete range of colorants for automotive and other industrial enamels and lacquers, and for rubber, plastic, printing ink, paper, and textiles.

Call for information and technical assistance

This booklet has described the wide range of Geon polyvinyl materials that are available and has touched upon some of their many applications. For specific technical information on their uses and how they can be successfully applied to your product or operation, send enclosed postcard or contact the nearest B. F. Goodrich Chemical Company Sales Office. We'll gladly help you select and apply the Geon material best suited to your needs.

Litho in U.S.A. June 1957

the PREFERRED material for 1,001 end-use products...

Cycolac is a lightweight, uniform resin, specially suited for the manufacture of any product which requires high-impact strength, light weight, non-corrosion and chemical resistance. Cycolac parts can be machined, much like other thermoplastics; threaded, sawed, milled, drilled, buffed, blanked, punched or sheared. It can be lacquered, enameled or printed and is easily bonded or cemented to itself.

lightweight...
Lightest of all rigid thermoplastics. Sp. Gr. 1.01.

chemical resistance...
Especially resistant to battery acids; equally effective against many oils, solvents and other corrosive chemicals.

good electrical properties...
Exemplified in electrical device which enables linemen to open switches on heavy power lines.

high impact strength...
Tested and proved to endure extremely rough usage and severe punishment.

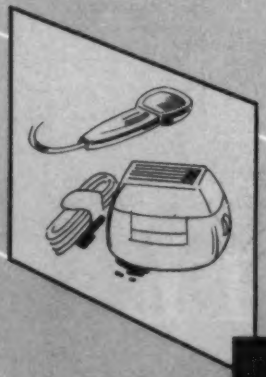
FIBERFIL



lifts the limits on markets for injection molders!

Since the introduction of FIBERFIL — just a few short years ago — applications of these glass-reinforced injection molding compounds have multiplied nationwide. Logically so, too, because FIBERFIL's unique physical properties removed limitations imposed by non-reinforced plastics to open up a boundless field of business for injection molders. Here for the first time were higher compressive strength and heat resistance, better control over mold shrinkage and warpage . . . qualities that make both FIBERFIL Styrene G and FIBERFIL Nylon G unexcelled for applications demanding exceptional accuracy plus outstanding impact strength and durability. Here, in fact, was (and is) the master key to brand-new profits for molders and better products for manufacturers.

More and more millions of pounds of FIBERFIL molding compounds are being produced to meet ever-mounting demand. Study the outstanding properties detailed on pages that follow — and you will see why.

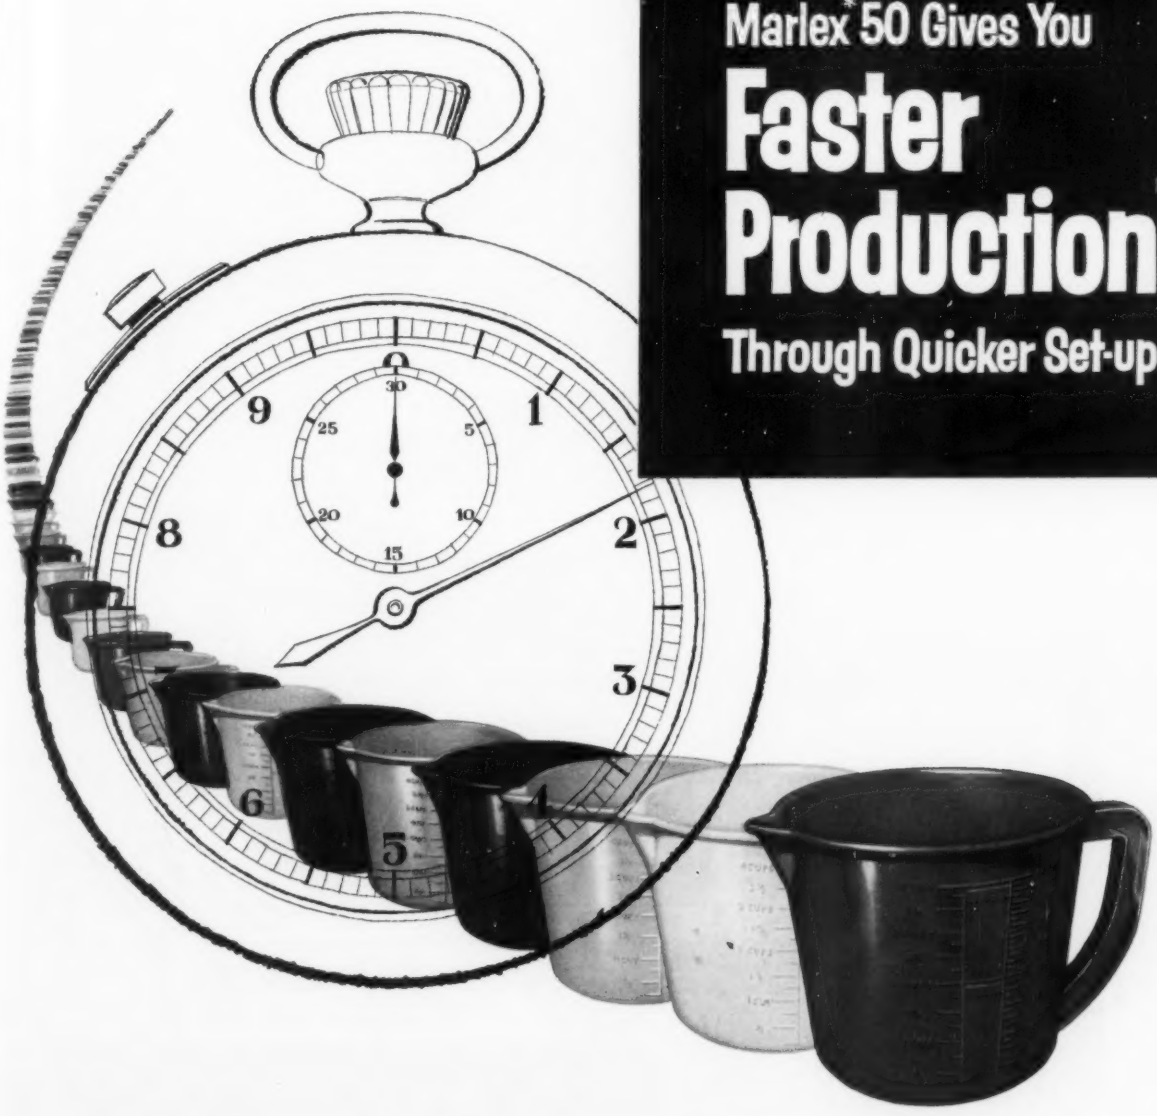
"Prestressed" Strength...

solid foundation for building ever-greater productivity and ever-better profits by injection processes

THE same basic principle of the prestressed beam, an advancement launching a new era in construction practices, has made *reinforced* FIBERFIL today's most significant contribution to the plastics industry. Because it more than doubles the precision, permanence, and strength of products that can be injection-molded . . . and is proving successful in more and more applications that could not be mastered with ordinary plastics . . . demand for FIBERFIL is already running millions of pounds and growing rapidly.

You, too, can build both present sales and an ever-brighter future — upon the solid foundation of FIBERFIL's *Reinforced Insurance.*

Whatever the product or part, however close the tolerances or however exacting the requirements for durability, don't decide it cannot be injection molded until you investigate FIBERFIL. Write, wire, or phone for further information.



FIBERFIL

Reinforced Insurance

for all injection molding!

FIBERFIL, Inc. • FOX FARM ROAD • WARSAW, INDIANA

Marlex* 50 Gives You Faster Production Through Quicker Set-up

Because MARLEX 50 sets up at higher temperatures than conventional polyethylene, your molding cycle can be speeded up. And the greater strength of MARLEX permits the use of *less resin* to achieve desired rigidity, so you get more items per pound of material. These are important manufacturing economies.

Greater strength, greater ability to withstand heat and cold, superb resistance to penetration by moisture, gases, oils and chemicals . . . all these qualities make possible the manufacture of many new and better products from MARLEX. Write your nearest Phillips Chemical Company office for further details.

*MARLEX is a trademark for Phillips family of olefin polymers.

FORMACOLOR*

THE SUPERIOR COLOR CONCENTRATE FOR INJECTION MOLDING

Color-power is sales-power. Those pellets of FORMACOLOR give your finished product the bright color, the RIGHT color, the color with the impact and the stop-look-and-buy appeal.

All the approved pigments required to achieve a rich and uniform finished color are contained in FORMACOLOR. It's made to be diluted at a ratio of **four to one** and costs no more than, a few pennies a pound.

Westchester Plastics, Inc. knows that at the consumer level, the color of the bottle is as important as the product it contains. FORMACOLOR is one of the many color concentrates, for polyethylene and most other thermoplastic materials, prepared by Westchester with this aim in mind . . . to command consumer attention. Advise us of the resin you intend to use and the color you need. We will forward you a sample for evaluation by your staff.

remember! the color makes the SALE!

Custom Compounders of Polyethylene Molding Powder and other Thermoplastic Materials

Manufacturers and Developers of Unicolor and Formacolor

*Pliothene. Formacolor, Unicolor® T.M. Reg. U.S. Pat. Off.

Grumman S2F, new Navy sub destroyer, has wing-tip and tail-fin parts made with HETRON-based material. Glass reinforcing mat is supplied to the fabricator in convenient roll form, pre-impregnated with resin.

If your reinforced plastic product must be strong . . . beautiful . . . fire-

Fire retardance, strength, and excellent molding properties combine in HETRON to give you a versatile material you can often use even where conventional polyester resins would not be applicable.

While fire retardance is frequently desirable in a part, it is by no means the only reason for specifying HETRON. Often HETRON is chosen for its other physical, chemical, and electrical properties, closely matched to the increasingly strict quality requirements for reinforced laminates in today's market.

Excellent physicals

Tests show that you can incorporate desirable physical properties in your product in highest degree with HETRON resins.

Table I, upper right, compares typical physical values for 0.1" laminates made with HETRON and with 10 other leading polyester resins. In this comparison HETRON 92, a rigid resin, surpasses the average of the 10 non-fire-resistant rigid resins in almost every property shown.

Values for two semi-rigid resins, HETRON 32A and HETRON 33, also shown in Table I, compare favorably even with those for the rigid resins. Low water absorption, excellent wet-strength retention, and, for HETRON 32A, an exceptionally high heat distortion point, are features of these resins.

For comparative purposes, Table II, upper right, lists typical properties of slightly heavier ⅛" laminates made with HETRON 92 and HETRON 32A.

Inherently self-extinguishing

HETRON laminates are self-extinguishing. They will burn at the point where a hot flame is applied, but snuff out as soon as the flame source is removed.

Typical daylighting panels made with HETRON, for example, test within a range of 20 to 75 in flame-spread rating, by procedure ASTM E84-50T (Tunnel Test). This compares with ratings of 100 for red oak, and over 400 for conventional unfilled polyester resins.

Flame retardance is chemically locked into the resin, through tight bonding of chlorine atoms in the molecule. This unique, inherent flame retardance is obtained without additives and consequently without loss of desirable mechanical properties.

Chemical resistance

HETRON resins exhibit excellent resistance to chemical attack. Immersion tests in water, dilute hydrochloric acid, 60% sulfuric acid, dilute sodium hydroxide, and kerosene, over a range of temperatures and for time periods ranging up to 60 days, produce little or no weight change in the cast unfilled resins.

Electrical properties

For the electrical designer, HETRON offers very low loss factor over a wide range of frequencies; dielectric constants generally lower than with other polyesters; relatively little change during long exposure to high humidity.

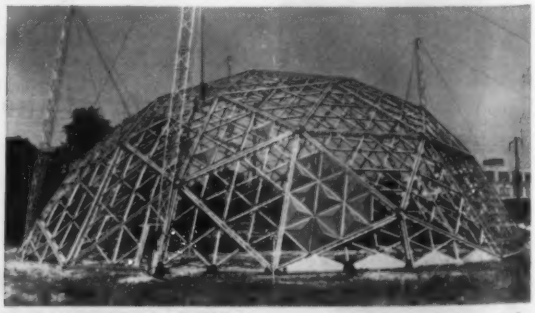
A growing use of HETRON is in glass-reinforced insulation for heavy-duty switchgear, where HETRON's fire retardance, strength, arc resistance, and other electrical properties contribute to improved design, safety, and high operating efficiency.

Molding advantages

You get an exceptionally smooth, well-filled surface when you mold with HETRON. This smoother surface can often reduce fabrication costs; it has cut hand-finishing time on parts by as much as 50%.

HETRON provides a good base for alkyd finishes. Parts can be baked at 350° F for 90 minutes without cracking or crazing.

Military applications



HETRON is being used in military aircraft parts such as wing tips, tail fins, window frames, air ducts, battery trays, radomes, and antenna covers. It is specified for 55-foot radomes used in perimeter defense, and for 40-foot landing craft hulls.

HETRON 92 and semi-rigid HETRON 32A are manufactured to meet Military Specification MIL-R-7575A, Types I, II, and III.

For complete information on HETRON resins, send for technical data sheets listing properties of the liquid resins, cured unfilled resins, and glass-cloth laminates. They include recommendations on handling and curing, and other useful information.

Fire-Retardant Daylighting Panels, made with HETRON by 10 major fabricators, carry U.L. label and Factory Mutual seal of approval based on exhaustive flame tests.

Jet Plane Hangar with HETRON skin for strength and fire safety can be erected and taken down rapidly, yet withstands winds up to 150 mph.

I. COMPARATIVE PHYSICAL CHARACTERISTICS

HETRON vs. 10 non-fire-retardant resins

property		rigid resins		semi-rigid resins	
		Hetron 92	avg. 10 others	Hetron 32A	Hetron 33

HOOKER CHEMICALS PLASTICS

Here's how (and why) wise processors use Diamond VINYL RESINS

Product	Specific Viscosity ASTM D-1243-52T	How to use	Why
DIAMOND PVC-50	0.44	Wire and Cable Insulation Profile Extrusions Calendered Film	Underwriters' Laboratories accepted as an interchangeable vinyl resin Excellent dry blending properties, high clarity and low gel particle count Superior heat stability A high molecular weight resin for optimum physical characteristics
DIAMOND PVC-45	0.38	Calendered Film and Sheeting Profile Extrusions Injection Moldings	Excellent dry blending, heat stability and clarity with low gel particle count Medium molecular weight offers easy processing
DIAMOND COMPOUND R-4		Type I Rigid PVC fittings, valves and pipe Calendered Rigid PVC Sheeting	Approved by National Sanitation Foundation Superior heat stability and easy processing characteristics permit use in conventional molding equipment Superior chemical resistance
Miscellaneous Plasticized DIAMOND PVC Compounds		For all types of extruded and molded products	Tailored compounds to meet customers' processing and end use requirements

Vinyl Processors like Diamond technical service, too

For two reasons: (1) our Plastics Products Laboratory evaluates and improves resins so that DIAMOND, and our customers, can make better products; (2) DIAMOND technical service is available to users, anywhere.

Only high quality can explain quick success in a hotly competitive market. DIAMOND technical service can help you put that quality to work in your products. We're ready to work with you now. Call your nearby DIAMOND sales office or write DIAMOND ALKALI COMPANY, 300 Union Commerce Building, Cleveland 14, Ohio.

Diamond Chemicals

Catalin

Industry's Dependable Quality-Source for Industrial Resins and Molding Compounds!

CATALIN molding and extrusion compounds . . . Styrene, Polyethylene and Nylon . . . each available in a wide range of formulations, figure prominently in the end-use product progress being made by today's plastics industry.

Of equal importance is the pioneering role that CATALIN has played in the research and development of urea, phenolic, cresylic, resorcinol and melamine resin formulations for industrial processes. Furniture, plywood, structural timbers and particle boards have achieved new usefulness because of CATALIN adhesives. Industrial and decorative laminates; rock wool and glass fibre insulations; crease resistant textiles; wet strength papers—all owe their improved properties to CATALIN bonding and impregnating resins. So, too, do grinding wheels and abrasive papers; brake linings; clutch facings; cork sheets; rods and tubes; oil filters; foundry shell molds and cores.

The immediate availability of CATALIN Molding Compounds, Industrial Resins and the newer Antioxidants, too, is a CATALIN-customer satisfaction factor. Thru the operation of three plants in the East, Midwest and South . . . and via strategically spotted warehouse facilities . . . supply requirements keep apace of nationwide demand. Result?—an excellent industrial relationship . . . a *mold-and-bond* that daily grows stronger.

CATALIN CORPORATION OF AMERICA

GREX*

*TRADEMARK FOR W. R. GRACE & CO.'S POLYOLEFINS

W. R. GRACE & CO.
POLYMER CHEMICALS DIVISION

Plant
Baton Rouge, La.

Offices
Clifton, N. J.

This ponderous machine, invented by one of our artists, not our engineers, may not be very practical but it does help us to illustrate the great versatility of GREX, the high density polyethylene. This versatility offers to molders, extruders and fabricators properties not found in other plastics. The unusual strength, high heat resistance, and exceptionally low moisture vapor transmission rate of GREX make it ideal for numerous applications both current and new. What can you make of this? Write today for more specific information.

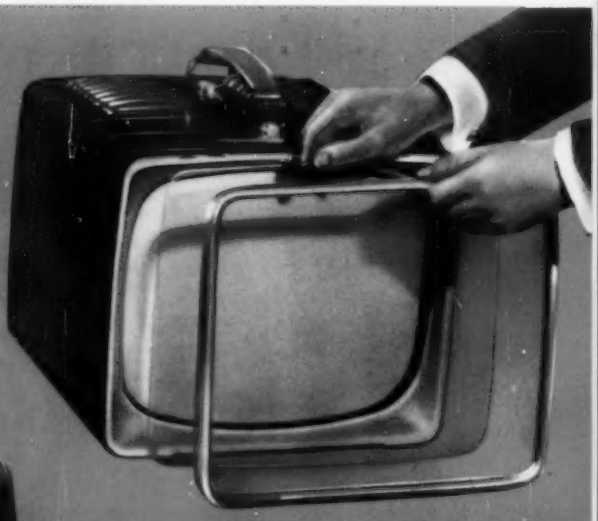
How to figure your sales potential in the plastics field

FREE . . . 40 page brochure will help you find answers to your questions about sales opportunities in the fast-growing plastics field.

This new study contains the inside story of one of America's fastest growing industrial markets. It presents one of the most stimulating and detailed analyses of the plastics field that has yet been published. It's filled with up-to-date figures on the consumption and production of plastics materials, on the field's processing equipment requirements, on potential areas of growth. It lists hundreds of kinds of machines, accessories, chemicals and intermediates, supplies and special services for which the field is manifesting an ever-increasing appetite.



You will find this handsome brochure—file size, lavishly illustrated, 40 pages—a valuable addition to your business library. It may well point the way to increased sales for the industrial products or services that your firm supplies.

For your free copy of "The Plastics Field," simply address a note on your company letterhead to *Advertising Manager*, Modern Plastics, 575 Madison Avenue, New York 22, N. Y.

PLEXIGLAS MOLDING POWDERS

PLEXIGLAS is the trademark for acrylic plastic molding powders manufactured by Rohm & Haas Company. Because of the combination of gleaming beauty and rugged durability inherent in acrylic plastic, PLEXIGLAS is used to give added sales appeal and serviceability to a wide range of products. Manufacturers of cars, home appliances, lighting fixtures, personal accessories, and optical and electrical equipment have found that parts molded of PLEXIGLAS provide the answer to their most exacting decorative and functional requirements. These pages tell why.

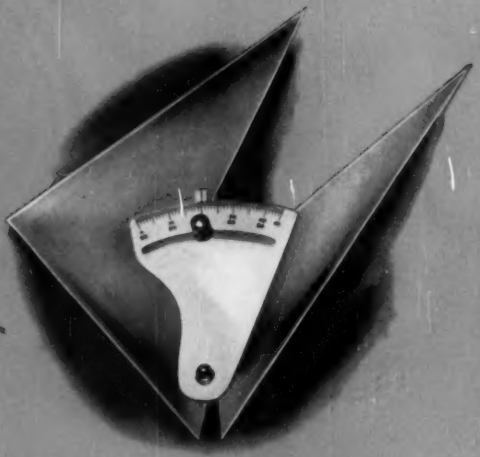
Characteristics of Molded Parts

CLARITY

Transparent moldings like this edge-lighted automobile indicator panel are crystal clear. Because of this freedom from cloudiness or haze, maximum efficiency is obtained in light-piping and other optical effects.

BRILLIANT APPEARANCE

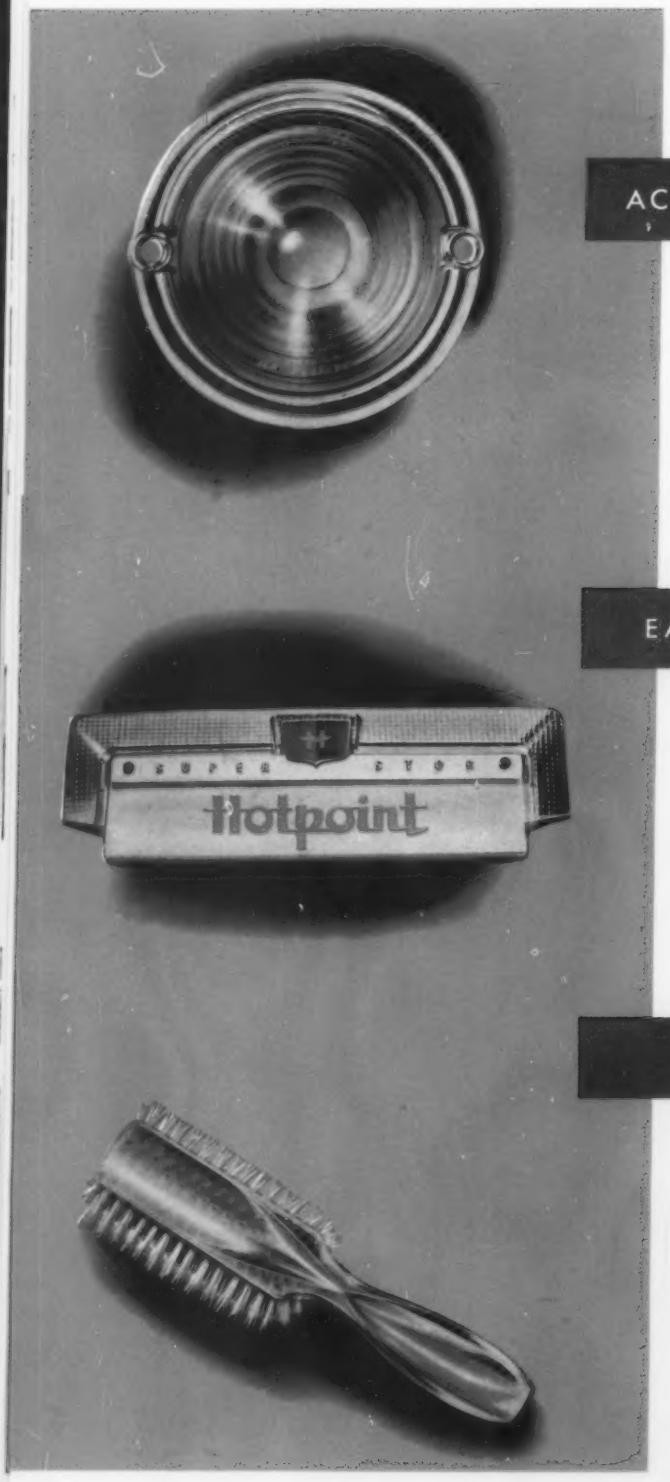
Plexiglas molded parts have bright, lustrous, sparkling surfaces that enhance the colorful appearance of three-dimensional insignia and name plates.



WEATHER RESISTANCE

Because Plexiglas is an acrylic plastic, unique among all plastics in ability to withstand exposure to weather, molded parts such as this exterior sign letter give long trouble-free service in outdoor applications. A wide range of colored powders are available, developed especially for outdoor stability.

DIMENSIONAL STABILITY



Plexiglas molded parts are notable for their freedom from shrinking or deterioration through long periods of use. The molding powders contain no plasticizers to leach out and have relatively low water absorption characteristics. Many types of precisely calibrated drafting instruments, where dimensional stability is essential, are molded of Plexiglas.

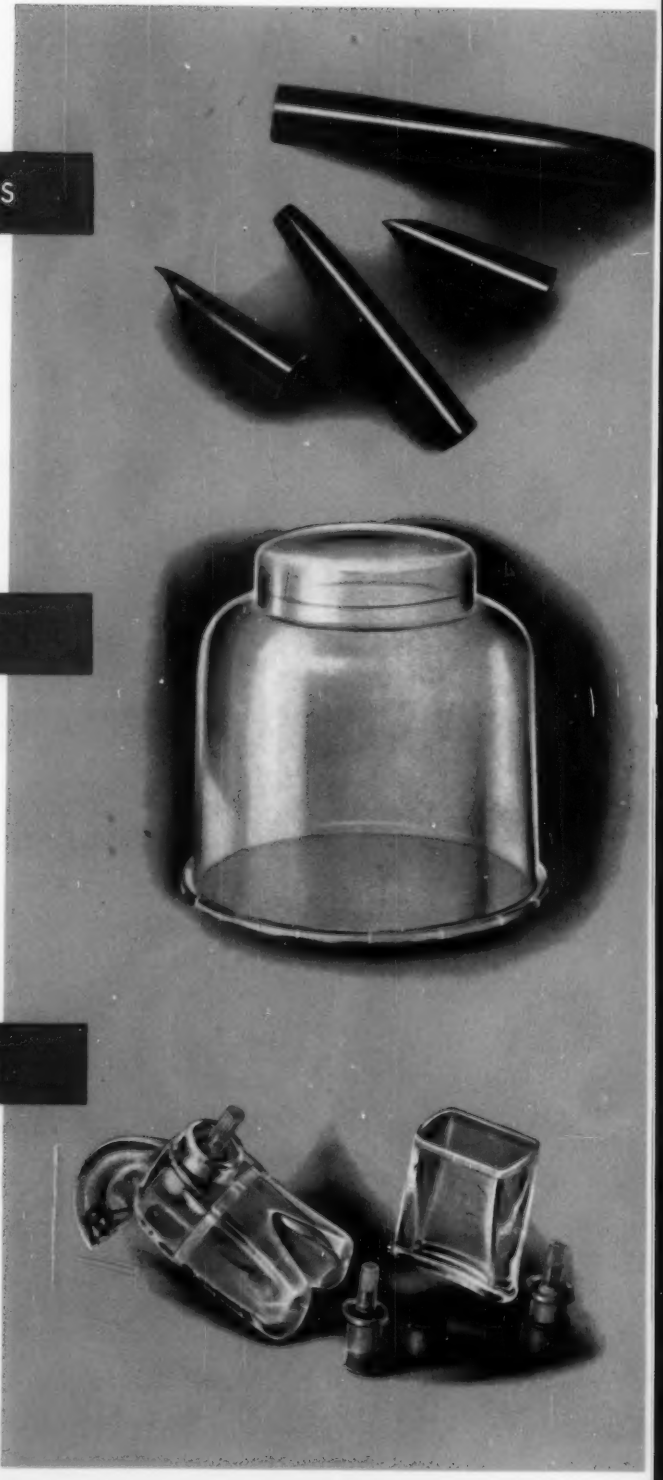
BREAKAGE RESISTANCE

Plexiglas imparts resilience and high impact strength to molded parts, enabling them to withstand hard blows and remain undamaged under rigorous service conditions. Tail light lenses on most motor cars are molded of Plexiglas.

ACCURACY OF MOLDING

Precise contours and sharp angles in molded parts such as automobile lenses are achieved with maximum efficiency by using Plexiglas. Molding accuracy can be sustained throughout large production runs.

EASE OF DECORATION



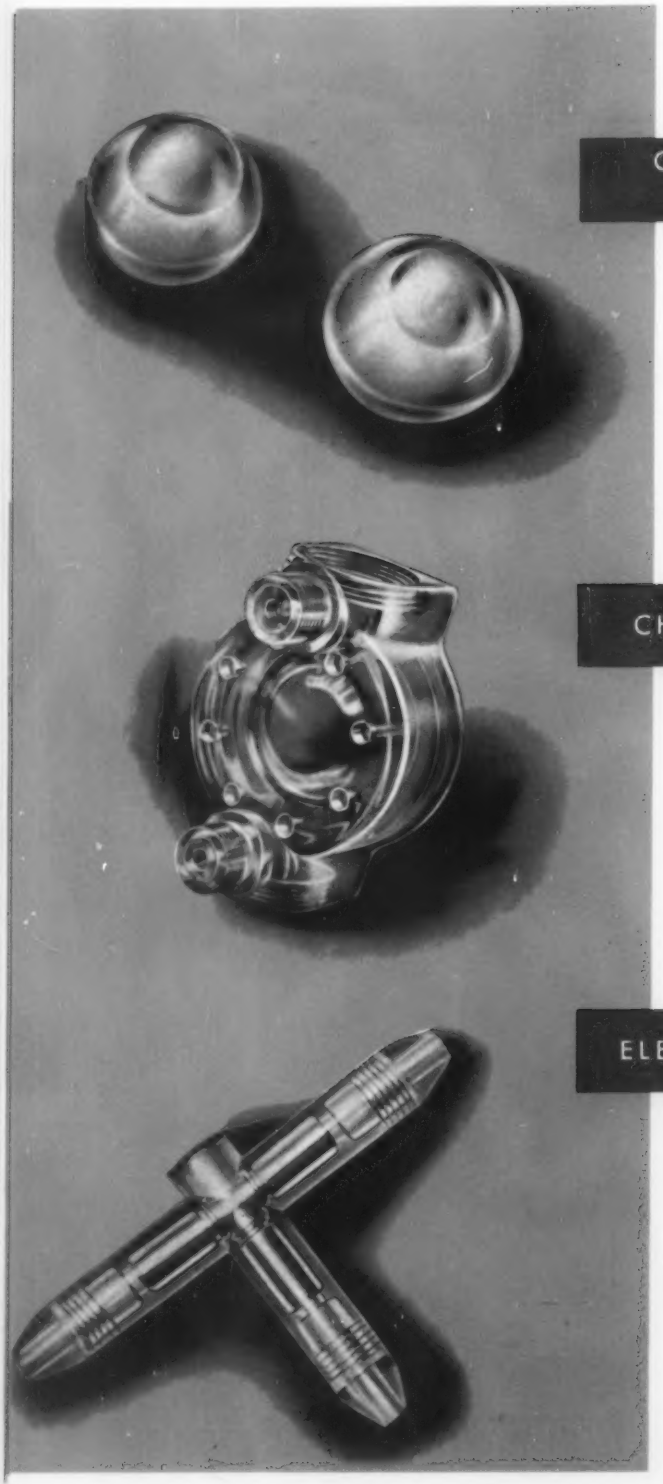
Paints and vacuum metallized coatings can be applied to parts molded of Plexiglas, resulting in efficient, high-yield production of three-dimensional, multi-colored parts such as trademark insignia.

MACHINEABILITY

Molded parts can be machined, drilled, threaded or routed with accuracy whenever such finishing operations are required. Multiple drilling of bristle holes in brush backs, for example, is performed without difficulty.

CHOICE OF COLORS

For integrally colored moldings such as fountain pen and pencil housings, a complete range of standard transparent, translucent, and opaque colored Plexiglas molding powders are available. Custom-matched shades are produced for special color requirements on volume orders.



TASTEFREE

Plexiglas molded parts are free of taste, and are used for various types of food and beverage containers such as this bowl of a fruit juice dispensing machine.

ODORLESS

Lack of odor is one of the reasons parts molded of Plexiglas are preferred for personal accessories, and articles such as this inhalator.

COMPATIBILITY WITH HUMAN TISSUE

Sensitive human tissue is not harmed by contact with Plexiglas moldings. Contact lenses are a typical example of applications where this characteristic is of particular advantage.

CHEMICAL RESISTANCE

An organic resin, Plexiglas is not affected by alkalies, non-oxidizing acids, salt water, photographic solutions, and chemicals used in treating water. It is attacked by alcohol, strong solvents, and fire extinguishing solutions. This valve is molded of Plexiglas because it must resist the corrosive effects of gaseous chloride.

ELECTRICAL INSULATION

Plexiglas molded parts are excellent insulators, with good resistance to arcing. Prolonged exposure to weather, or immersion in water, has practically no effect on electrical properties. This Plexiglas aircraft antenna fitting also permits easy inspection of antenna connections.

TYPES OF MOLDING POWDERS

Injection

Extrusion

Compression

This brochure contains detailed information on the design and use of molded PLEXIGLAS parts. It will be sent promptly on request. Ask for Booklet PL-159a.

This manual—Design and Fabrication Data—covers fabrication techniques and design considerations involved in the use of cast PLEXIGLAS sheets. For copies, ask for Booklet PL-28d.

CAST AND EXTRUDED SHEETS

PLEXIGLAS acrylic plastic is also made in the form of cast and extruded sheets in a wide range of sizes and thicknesses, as clear transparent material and in many colors. Sheets can be heated and formed to almost any shape and are easy to cut, machine and cement. They have the same advantageous performance characteristics as parts molded from PLEXIGLAS molding powders. Because of this, sheets are useful for prototypes of parts to be molded, design study models, transparent demonstration models, and for production runs in quantities where tooling costs for molding are not justified.

DESIGN SERVICES AVAILABLE

Services of the design staff of the Rohm & Haas Company Plastics Laboratory are available for consultation in the design of molded parts and sheet applications. For assistance in any idea or problem involving the use of PLEXIGLAS, call or write the nearest of the following sales offices:

In PLASTICS, the plant that does everything!

THESE PRODUCTS:

GERING "the Hose with the Mirror Finish."

GERLITE Extruded Acrylic Sheets, clear or colored, to 54" wide, to .125" thick, any practical length. For Illuminating Signs, Lighting Fixtures and Vacuum Forming Applications.

GER-FLEX Vinyl Tubing

GER-TUBE Polyethylene Tubing from 1/32" to 4" I.D., also special shapes and cross-sections.

DRYCOL on-the-spot, in-plant colorant for all thermoplastics.

S-T-R-E-T-C-H Polyethylene master-batch color concentrate.

STYROMIX Clear polystyrene dry-blended with color and lubricants, ready to mold.

GER-PAK Polyethylene film, sheeting, and tubing for packaging consumer and industrial products. Moisture-vapor barrier up to 20 feet wide, for use in light and heavy construction.

THESE SERVICES:

Molding Powders Division

We manufacture for standard and special applications, for injection and extrusion molding:
Polystyrene • Vinyls • Polyethylene
Cellulose Acetate • Ethyl Cellulose
Acrylic • Nylon

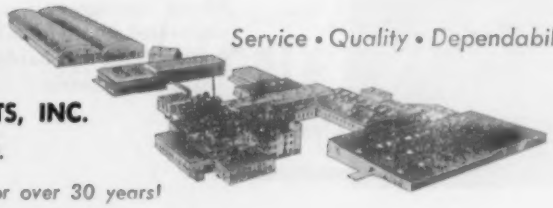
Extruded Products Division

Complete Department equipped with extruders from 2" to 10" with dies and take-off equipment to make Sheeting, Tubing, Rods, Pipe, Special Cross Sections and Shapes.

Custom Compounding

Complete facilities for top quality processing. Full staff of laboratory, technical and engineering personnel.
Polyethylene • Vinyls • Nylon • Acrylic • Cellulose Acetate • Butyrate Ethyl Cellulose • Polystyrene and its Copolymers

SCRAP RECLAMATION



Far ahead of any ordinary scrap reclamation is the job done at Gering. Our long experience coupled with skilled technical personnel enables us to work wonders with scrap sorting, separating, grading, decontaminating, blending, color matching, compounding, and pelletizing.

VYGEN®

MOLDING

VYGEN 105

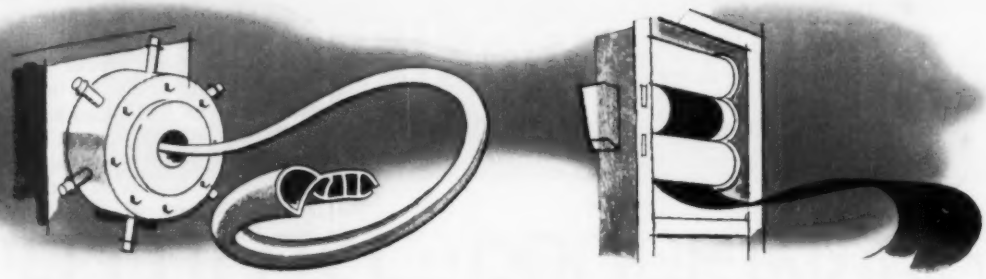
VYGEN 110

VYGEN 120

VYGEN 1101

VYGEN 2201

VYGEN 105—A lower molecular-weight resin for molding, calendering, and extrusions requiring a high-gloss finish. Especially well-suited for high-gravity light-embossed calendered sheeting. VYGEN 105 allows the use of lower processing temperatures.



VYGEN 110—A general-purpose, average-molecular-weight resin, adapted for easy processing of calendered film, sheeting and coated fabrics. Also recommended for molding and extruding operations where excellent heat and light stability are requirements.

VYGEN 120—A high-molecular-weight, general-purpose resin, ideally suited for dry-blend extrusion operations . . . blended with monomeric or polymeric plasticisers, this resin has an extremely rapid rate of solvation. VYGEN 120 has a narrow range of particle size distribution, producing extrusions free of gelled particles.

VYGEN 1101—A Type I rigid PVC compound for extrusion . . . comes ready for the extruder, offering a perfect balance between optimum chemical resistance and easy processing.

VYGEN 2201—A modified rigid PVC compound produced for calendering operations . . . easily processed on existing equipment. Can be pigmented for light colors, and has excellent flame resistance, high flexural modulus and hardness. Sheet is easily post-formed by deep drawing or vacuum forming.

The "FIRST FAMILY" of specialized PVC resins for specific application

EXTRUDING CALENDERING

General's Chemical Division foresaw the need in the plastics industry for specialized resins to meet specific requirements. Combining modern research methods with production "know how", the VYGEN family of top-quality PVC resins has been developed and tested to satisfy that need. No longer must you "take the closest thing"... now there's a VYGEN resin *just right* for *your* application, and delivery will fit the most demanding production schedules. To guarantee the finest finished product, select the VYGEN resin designed for your job . . . or write the Chemical Division for assistance.

Modern Plastics' Annual Editorial Index

(Index to Volume 34, September 1956 through August 1957)

You will find this extensively cross-referenced, sixteen-page Index a welcome time saver in locating editorial material that has appeared in a full year's back issues of the magazine. More than that, you'll discover that the Index increases the value of your file copies by providing a considerably more detailed breakdown of their contents—particularly of "buried" references within an article—than is given on the "Contents" page of individual issues.

The Cumulative Index is actually three indexes in one: a General Index of Titles, an Index of Individual Subjects and an Index of Authors.

The General Index of Titles is further subdivided into separate indexes of engineering and technical articles, and the Index of Individual Subjects alphabetically cross-tabs plastics product applications in two ways: by material of composition and by product name.

To get your copy, just fill out and mail the coupon

POLYOLEFIN THERMOPLASTIC

CELLULOSE ACETATE

CELLULOSE PROPIONATE

POLYESTER RESINS

ACETATE FILMS

ACETATE SHEETING

PVAc RESINS

CELANESE CORPORATION OF AMERICA, Plastics Division, Dept. 101 X, 744 Broad Street, Newark 2, N.J.

ACETATE MOLDING COMPOUNDS

DESCRIPTION

Celanese acetate combines high impact, tensile and flexural strength, shatter resistance, color permanence and freedom from objectionable odor. The material molds and extrudes readily with a high gloss finish. Available in a range of formulations and colors.

APPLICATIONS

Toys, shoe heels, appliance housings, jewelry, tool handles, sunglasses, brush backs.

FORTICEL MOLDING COMPOUNDS

DESCRIPTION

Forticel (cellulose propionate) offers an excellent balance of physical and mechanical qualities . . . good form retention, dimensional stability, high impact and tensile strength, weathering characteristics, unusually fine moldability, and freedom from unpleasant odor. Available in a number of formulations and range of colors.

APPLICATIONS

Pens, telephone housings, automotive parts, optical frames, business machine keys, vacuum cleaner attachments, transistor set cases.

MARCO POLYESTER RESINS

DESCRIPTION

Thermosetting liquid resins adaptable to a variety of fabricating techniques. Available in a number of formulations which can be blended to acquire specific physical properties in finished products. Tack-free cures at ordinary room temperatures. Cured Marco Resins exhibit excellent resistance to moisture, heat, weathering, and most chemicals. Special thixotropic formulations for hand lay up fabrication. Premix formulations based on MR Polyester Resins are also available.

APPLICATIONS

For boats, auto bodies, corrugated and flat sheet, housings, tank and tank linings, swimming pools, truck bodies, miscellaneous laminates, castings and coatings.

ACETATE SHEETING and FILM

DESCRIPTION

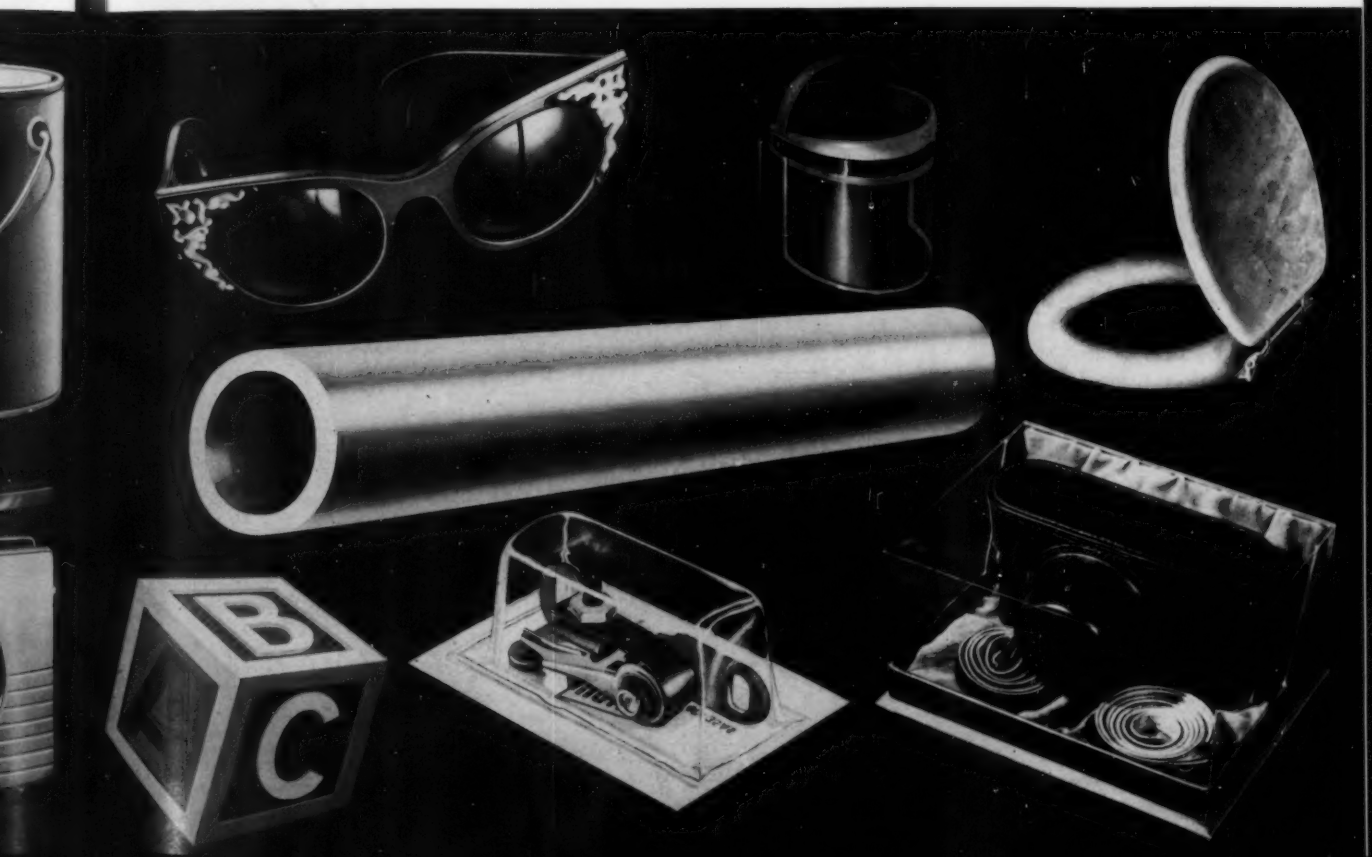
Celanese acetate sheeting and film offer crystal clarity, flatness, water and grease resistance, moisture vapor permeability, and excellent aging characteristics. Available in thickness from .0005" to 0.250"—continuous lengths and cut sheets —clear transparent, transparent tints, opaque colors and special effects.

APPLICATIONS

Ophthalmic frames, lamp shades, advertising displays, crystals, safety shields, goggles, visible office records, protective covers. For packaging of all types including vacuum formed and fabricated rigid transparent containers, backing for pressure sensitive tapes, sound recording tapes, metallic stamping foils, electrical insulation, and vacuum metallizing.

PVAc RESIN EMULSIONS

DESCRIPTION



Celanese polyvinyl acetate emulsions are milk white liquids with viscosities ranging from water-thin to extremely viscous. They are characterized by small particle size, excellent film strength and clarity. They are available as homopolymers and copolymers.

APPLICATIONS

Water-based latex paints for both interior and exterior use . . . adhesives . . . textile coatings and finishes.

FORTIFLEX A a new polyolefin thermoplastic

Fortiflex A is characterized by its toughness, rigidity and chemical resistance. Products made of this readily moldable thermoplastic exhibit excellent resistance to sterilization temperatures and flexibility at low temperatures. Applications include: bottles and containers, housewares, toys, sporting goods, packaging materials, and transportation, industrial and electrical products.

FORTIFLEX

high-density linear polyolefin plastic

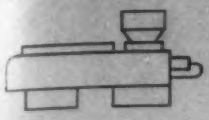
Fortiflex A, a new Celanese thermoplastic, is a high-density polyolefin plastic produced by low-temperature, low-pressure process.

This process produces polymers having linear chains with less branching than conventional polyethylene, resulting in:

- **improved rigidity with greater strength**
- **harder surface with excellent surface finish**
- **lower permeability to moisture and most gases**
- **ability to withstand from below zero to sterilization temperatures**

Furthermore, the fine qualities that have made polyethylene the outstanding plastic of this decade are inherent in Fortiflex A:

- **resistance to chemical attack**
- **excellent electrical characteristics**
- **colorability, moldability, economy**



These properties, plus the fact that this plastic type has sanction by the Food and Drug Administration for use in contact with food, promise Fortiflex A a major role in housewares; packaging; refrigerator parts; toys; gears, housings and parts; medical equipment.

Fortiflex A is available now in commercial volume from conveniently located terminals in major industrial areas. Write Sales Development Department, Celanese Corporation of America, Plastics Division, 290 Ferry Street, Newark 5, N. J., for complete details.

BCI NYLON RESINS SERIES 800

THE MOST VERSATILE NYLONS EVER PRODUCED!

Used in extrusion, injection or compression molding, water dispersion or solvent solutions.

- **thermoplastic or thermosetting**
- **flexible without plasticizers**
- **high strength and elasticity**
- **barrier to hydrocarbon solvents**
- **exceptional abrasive resistance**
- **heat sealable**

Look for forthcoming news of BCI's expanding range of nylon resins for extrusion as well as injection molding.

Should additional data on BCI nylon resins be desired, we will welcome your inquiry:

BELDING BCI CORTICELLI INDUSTRIES

1407 BROADWAY, NEW YORK 18, N.Y.

To commemorate

25 YEARS OF

Since the first Tenite plastic was sold in 1932, the trade name, Tenite, has come to symbolize the utmost in quality, color and service. *Tenite plastics*—Butyrate, Acetate, and Polyethylene—are produced at the highest quality levels possible. *Tenite colors* are unmatched for brilliance, durability and range. And *Tenite service* is well known throughout the industry for its effective thoroughness.

While 25 years would be only one of many milestones in most industries, in the young and vigorous plastics industry Eastman's quarter-century actually spans the modern era of thermoplastics and injection molding. The medallion shown on the opposite page has been created to mark the occasion of our 25th Anniversary as a producer of thermoplastics, and to commemorate our long association with the plastics industry. We hope this souvenir medallion, which is injection molded of Tenite Butyrate, will remind our many friends of our long experience in their field.

TENITE PLASTICS

1932—Tenite Acetate introduced. The original Tenite plastic, offering a wide range of desirable properties, including toughness, light weight, impact strength, enduring luster and low heat conductivity. Available in a variety of formulations and almost unlimited colors. Typical uses: shoe heels, appliance housings and parts, toys, novelties.

1938—Tenite Butyrate introduced. Extremely tough, high in impact strength, resilient, lightweight, lustrous, weather-resistant, dimensionally stable. Available in a wide variety of formulations and an almost unlimited range of crystal, transparent, translucent, opaque, metallic and variegated colors. Typical uses: steering wheels, business machine keys, tool handles, telephone housings, football helmets, industrial pipe, toys, marine floats.

1954—Tenite Polyethylene introduced. Virtually unbreakable, chemically inert, resistant to water and moisture transmission and to strong acids, excellent insulator. Available in spherical pellets, in natural or wide range of colors and colored concentrates, with or without antioxidant. Typical uses: housewares, toys, packaging film, pipe and tubing, wire and cable covering, coating for paper, film and foil.

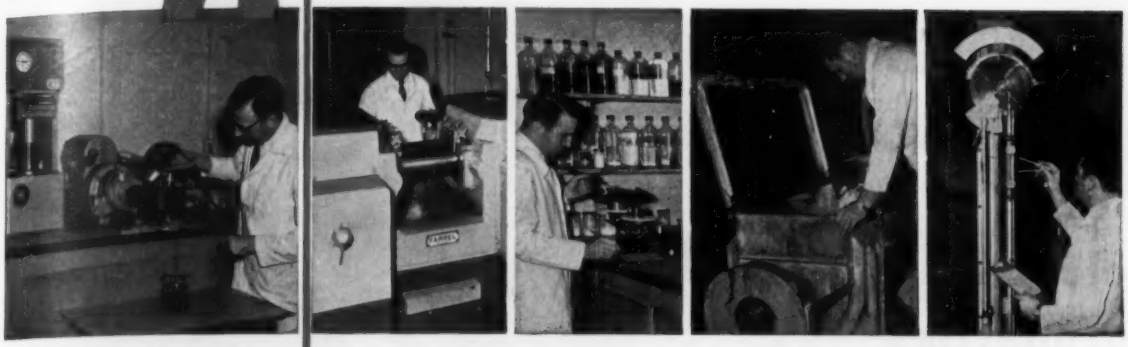
BESTWALL®

GYPSUM PLASTERS

SOLD THROUGH

BESTWALL CERTAIN-TEED SALES CORPORATION

120 East Lancaster Avenue
Ardmore, Pa.



EXPORT DEPARTMENT:
100 East 42nd St., New York 17, N.Y.

CUSTOM MADE PLASTER

Whatever your requirements, Bestwall and its distributors are ready to work closely with you, and to recommend the specific industrial plaster that will improve your product or raise your plant efficiency. Write or call General Office, Ardmore, Pa.

POTTERY PLASTERS **K-56**	For general mold work in potteries as jigger molds, casting molds, and in mold and model work. Also used for casting art objects such as plaques, statues, novelties, etc.	This plaster is especially treated during manufacture to give it unusual surface hardness in the set state, providing long mold life at lower production costs. Compressive strength at pouring consistency (dry cast): 2300 psi.
K-62	An extra fine ground pottery plaster designed to give the best possible results in mold wear. A premium product.	Treated for shock resistance. Powder is white but gives light blue color in slurry and cast. Produces the most durable, strongest cast of any pottery plaster. Compressive strength at pouring consistency (dry cast): 3200 psi minimum.
SUNFLOWER MOLDING PLASTER	Sunflower Molding is used for shop cast ornamental work, statuary, plaques, novelties, terra cotta and Portland cement molds.	Made from high purity rock with lower water requirements than regular gypsum plasters, giving strong casts at pouring consistency.
INDUSTRIAL DENSITE K-6 (High Expansion)	For casts that demand extremely high strength and low water absorption. Perfectly suited for use with mold materials such as wood, plaster, rubber, clay, metal. As a conditioner for ordinary plasters to obtain intermediate strength.	The strongest and hardest pure gypsum plaster available. At pouring consistency, the tensile and compressive strengths and surface hardness of the dry casts are about five times those made of ordinary plaster. Compressive strength at pouring consistency (dry cast): 9000-10,000 psi.
LOW EXPANSION DENSITES **K-12**	For case and block molds, patterns and models where great strength, hardness and wear resistance are desirable in a low-expansion material.	This is the strongest, hardest low-expansion plaster available today. Its amazingly low expansion—.03 to .04%—makes it ideal where accurate dimensions must be maintained. It has a normal period of fluidity and plasticity. May be mixed with ordinary plasters of intermediate strength and expansion. Compressive strength at pouring consistency (dry cast): 6000 to 7000 psi.
K-12-F	For detailed case molds, patterns and models or wherever an extremely fine grind low-expansion plaster is indicated.	Where extreme sharpness of intricate detail combined with unusual surface smoothness is desired, this fine grind version of Densite K-12 is now available. This is the finest grind low-expansion plaster obtainable today. Excellent for production of superior case molds.
K-17	For all types of patterns and molds where dimensional stability, high strength and low heat generation are important such as splash casts over wood models.	A Densite formula of a low setting expansion .04-.05%, high strength up to 10,000 lbs./sq. in. and low heat generation. Dimensionally stable.
K-25	For pattern and model work where plaster has to be rodded to a contour or where shell casts are taken from a master mock-up.	A Densite formula made plastic so that it is easily built up on curved and vertical surfaces. Low setting expansion and high strength.
BREAKAWAY PLASTER	Usable for expendable mandrels that can be readily broken up and removed.	A special gypsum plaster of high water carrying capacity and relatively low strength. Set casts will disintegrate and can be removed with hot water or steam.
CERTROCK	For case molds. Its high fluidity reproduces the finest details, assuring extremely smooth, non-porous surfaces on finished molds.	A high purity gypsum plaster with over twice the tensile and compressive strength of standard plasters, resulting in little breakage. Compressive strength at pouring consistency (dry cast): 4500 psi. (*Note: This plaster cannot be built up or carved.*)

A. Schulman, Inc. answers today's biggest plastic question . . .

Why are so many molding and extruding plants buying

LABORATORY CONTROLLED

processed vinyl and polyethylene?

Because they're saving money. Our processed vinyl and polyethylene DO cost less, but at the same time, precise laboratory control assures a product of the highest quality. Working with modern methods and machines, we are able to fill your raw material orders to EXACT specifications, at definite savings to you. HOW?

We maintain complete laboratory equipment of the very latest type, and a staff of highly skilled technicians checks the quality of vinyl and polyethylene we buy, then keeps a constant watch on our processing. Whether you do molding or extruding, we are in a position to handle your requirements . . . just let us know what product you make and give us your specifications.

There is NO GUESSWORK involved — and it COSTS YOU LESS.

Samples mailed on request.

If you make products like these you can depend on A. Schulman, Inc. laboratory controlled polyethylene and vinyl. **A TRIAL ORDER WILL CONVINCE YOU!**

properties

DAPON® resin

superior moisture resistance

Completely protected and locked-in—the excellent electrical properties inherent in cured DAPON resin are protected by the *resistance* of DAPON resin *to moisture in all forms.*

DAPON resin is the *new prepolymer* of diallyl phthalate—a dry white powder with improved properties. It is *easy to handle and store.* Its advent has made possible the use of diallyl phthalate in *all processing methods* for thermosetting resins.

Because the cure of DAPON resin involves addition polymerization, and not condensation, *moisture formation is non-existent* during cure.

Think of an electrical connector with *volume resistivity higher than that of porcelain* with complete protection that guarantees the retention of these properties under the most adverse conditions. This is DAPON resin.

Rid yourself of the moisture problem. Be assured of locked-in initial properties and locked out moisture. *Write now for technical literature containing properties, uses and methods of application for DAPON resin.*

WHERE POLYETHYLENE IS USED...

A-C® Polyethylene ..... delivers • QUALITY! • SAVINGS! • SPEED!

...for INJECTION MOLDING

Molders who use A-C Polyethylene in their operation gain distinct competitive advantages. Controlled gloss, better color dispersion, and the ability to run larger, more intricate parts are the definite product advantages. Faster cycles, positive mold release, lower operating temperatures and less overall machine maintainance, are the profit-making features contributed by the controlled flow possible with A-C Polyethylene. By simply changing the percentages of A-C Polyethylene, you can greatly reduce the variety of polyethylene grades required in inventory and still have control of resin flow characteristics to meet all kinds of molding problems.

...for FILMS, PLAIN AND COLORED

In the extrusion of Polyethylene films, adding A-C Polyethylene gives faster rates, lower extrusion temperatures, lessens machine stress, and makes gauge control easier.

For colored film, A-C Polyethylene is invaluable for even, streakless pigment dispersion. Colored films using A-C Polyethylene dispersed color pigments are strikingly brilliant and uniform.

...for SLUSH MOLDING

A-C Polyethylene offers an entirely new material for slush molding. With this new polymer you can use less expensive molds, get faithful mold reproduction with fine detail and the finished part has a warm, "life-like" feel. Finishes from dull to high gloss are possible.

...for COATINGS

Coatings containing A-C Polyethylene give a hard, scuff-resistant, glossy surface. Excellent low temperature flexibility and the elimination of blocking problems are added attractions to the converter.

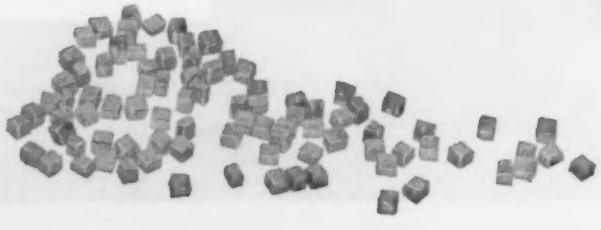
Bread and frozen food wraps are glossy and scuff-resistant.

Shipping cartons are grease resistant and need no liner to protect contents from fibre scratchings.

Butter and frozen food cartons, and bakery cartons are grease resistant and feed as single units to automatic packaging machinery.

POLYETHYLENE FOR POLYETHYLENE!!

A-C Polyethylene is a low molecular weight polymer of ethylene with a high melting point but a low melt viscosity. You can add A-C Polyethylene to other polyethylene resins with complete confidence in their compatibility. The improvements in product quality, the operational savings, and the production advantages derived from varying percentages of A-C Polyethylene, give you a flexibility in raw material which is unique in plastics operation. No special equipment is required to take advantage of A-C Polyethylene.



Two Forms — Range of Grades

A-C Polyethylene is available in two forms to meet a variety of production methods. For ease of handling the uniform cubes, as illustrated here, meet most requirements. A finely powdered form, called "atomized," is especially suited for certain more difficult blending operations. You can obtain either a hot melt polyethylene or water emulsifiable grade of this unique material depending upon the specific needs of your operation.

Write today for complete information. We will be glad to demonstrate the proven advantages of using A-C Polyethylene.

Plenco
PHENOLIC MOLDING COMPOUNDS
Plenco engineering and chemical research is a continuing factor in the development of new uses for phenolics in the manufacture of high quality products. We welcome the opportunity to show you how many of the country's leading molders have solved their most exacting product and production problems . . . through a wide range of quality-tested Plenco compounds and resins.
NEW FORMULATION!
Plenco 476
Semi-impact molding compound with improved water resistance and dimensional stability.
After 120 hours of continuous boiling in a 3% commercial detergent water solution, Plenco 476 has a total moisture gain of less than 2%. Dimensional change less than 0.5%. An additional 240 hours of continuous exposure to boiling produced no further gain in weight or dimensional change. Applications of Plenco 476 include vaporizers, dishwasher and washing machine components, blowers, humidifiers, water pump impellers, etc.
Serving the plastics industry in the manufacture of high grade phenolic molding compounds, industrial resins and coating resins.

In the light of recent developments in the field, foamed plastics now stand out as one of the most exciting and fastest growing segments of the plastics industry. As a guide to the activities in this complex area, this section is devoted to a complete review of all commercially available rigid and flexible foams.

FOAMED VINYLS

Applications
(Open Cell)

BY HENRY E. ALLEN*

Flexible, open-cell vinyl foam is by far the most important and largest-volume type of expanded or cellular vinyl material on the market today. All open-cell, flexible vinyl foam (OFVF) is based on variations and modifications of the well-known and widely-used vinyl plastisol technology. The versatility of OFVF is possible because, with the plastisol technique, the basic vinyl resin characteristics can be modified or varied by mixing the resin with a wide range and combination of plasticizers. Important variations and unusual versatility may be obtained by varying both the total plasticizer-to-total resin ratio and the ingredients of the plasticizer system. Further property variations, particularly of density, may be obtained without changing the formulation by merely varying foaming process conditions.

Cushioning characteristics

The most important functional property of any open-cell flexible foam is its comfort as a cushioning material and its durability. In determining the value of a cushioning material, the consuming public seems to like a combination of softness and firmness, plus resilience and comeback without bounciness. Engineers, thus far, have been unable to come up with wholly adequate measurements of these attributes. The flexible vinyl foam committee of the S.P.I. Cellular Plastics Div. has approved a tentative specification and test procedure for measuring compression resistance or indentation load deflection, but these single point deflection readings (25%) provide only a measure of hardness, and not a means of measuring or of assaying the actual feel or resilience that the user wants. The important fact is, however, that through careful formulation (which includes resins, plasticizers, stabilizers, pigments, and surface active agents) vinyl foam can provide the desired characteristics for both the comparatively soft and springy cushioning required for comfort in home furniture, and the firmer and greater energy-absorbing type of cushioning called for in transportation seating where road and roadbed conditions significantly affect comfort.

The most important service requirement of any open-cell flexible foam cushion is that it maintain its original dimensional and load-carrying ability during the lifetime of the product of which it is a component. A flexible foam cushion that permanently loses thickness under service conditions

Recent Developments and References were prepared by the editors.

Foamed polyethylene (*Agilene-*, American Agile Corp.), available in such semifinished molded components as rings, blocks, rods, and sheet, may be used in heat and electrical insulation, soundproofing applications, and the like. The foam has a specific gravity of 0.46, is unicellular, light in weight, and extremely buoyant. It has a tensile strength of 500 to 600 p.s.i. and good compressibility.

Silicone foam rubber (*Cohrfoam,* The Connecticut Hard Rubber Co.) is light in weight and remains soft and resilient over a temperature range of —100 to 480° F. It can be molded into complex shapes and has already found application as airframe seals where no other material has been found successful.

Continuous urea-foam equipment (W. H. Kreidl) produces about 270 cu. ft./hr. of urea foam of a density of 2½ to 4 lb./cu. foot. One unit produces granules for insulating purposes. Another type makes bats or strips. These strips are still appreciably thermoplastic as they come out of the dryer, and are warm-pressed to the desired shapes and surfaced with plastic sheeting. They are used as insulating mats for the building trade and for appliances, as well as for packaging of breakable and friable goods.

Sponge plastisols (Stanley Chemical Co.), made from vinyl resins and chemical blowing agents, may be of open- or closed-cell construction, atmospherically or pressure blown, with variations in toughness, compression resistance, and flame resistance. There are formulations for knifing, roller coating, hot and cold dipping, slush molding, and casting and pressure molding.

A new molding-in-place technique has been developed (The Dow Chemical Co.) for expandable polystyrene. This technique utilizes exothermic heat developed from the cure of thermosetting resins. Structural foams obtained by this technique are characterized by excellent dimensional stability, low water absorption, good low-temperature insulating properties, and the ability to bond to many different surfaces according to the developer.

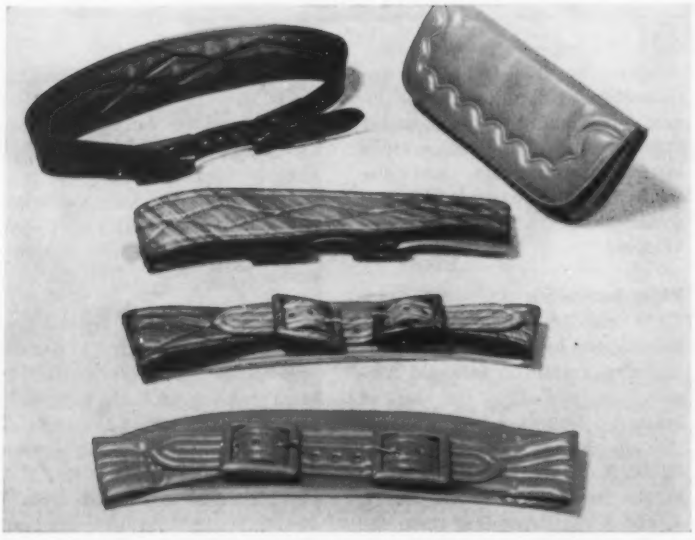
Pipe insulation (Mundet Cork Co.), molded from expandable polystyrene beads, for an air-conditioning system at Idlewild Airport, is probably the largest foamed polystyrene bead application to date. It involves about 20,000 ft. of pipe; the thicknesses of the insulation sections are 1, 2, and 3 in., depending upon the need.

Expandable polystyrene beads (*Dylite,* Koppers Co., Inc.) are used to produce 24-in. wide continuous slabs up to any practical length (Dyfoam Corp.). The planks are sold for insulation in cold storage warehouses, refrigerated trucks and railroad cars, sectional refrigerators, and building or residential construction.

Prefoamed blocks of epoxy resin (*DuRafoam,* D & R Pilot Plants, Inc.) are now available in sizes up to 1 by 2 by 6 ft. and in densities from 5 to 20 lb./cu. foot. The foams are easily machined and have compressive strengths of from 50 p.s.i. at the lower densities to about 1000 p.s.i. at the higher densities. Recommended uses are for check fixtures, templets, and models.

Flexible polyurethane foam with densities of 3 to 4 lb./cu. ft. can be produced at room temperatures in a matter of minutes using a two-component liquid system of polyesters and isocyanates. The manufacturer (Dayton Rubber Co.) suggests the use of this material for in-plant foaming of shoulder pads, toys, insulating materials for clothing, etc. A scale, mixing vessels, molds, and an exhaust fan are said to be the only necessary equipment.

A foamed, free machining, high-temperature epoxy resin (*Eccostock R 20,* Emerson & Cuming, Inc.) is completely unicellular and has an operating temperature range from —100 to 350° F. The specific gravity of this material is 0.61; the dielectric strength (volts/mil), 350; and the volume resistivity (ohm-cm.[3]), $10.^{14}$



A flexible urethane foam (Isocyanate Products, Inc.) with a load deflection curve similar to foam rubber and an extremely low compression set is suggested for use in the comfort seating field by the manufacturer. This foam can be produced from a two-component liquid system and can be either hand or machine mixed.

A polyester developed for the production of urethane foams (*Witco Fomrez No. 50,* Witco Chem. Co.) has both a narrow hydroxyl number and viscosity range and a uniformly low moisture content. It produces reproducible, uniform urethane foams.

New polyethers (*Pluronic* and *Tetronic,* Wyandotte Chemicals Corp.), based on ethylene and propylene oxide, are available for reaction with isocyanates to make urethane foams. They are lower in cost than other polyethers and also cheaper than adipic-type polyesters.

Foam made from polyether resin (*Teracol 30,* Du Pont) has more softness, greater freeze resistance, higher resiliency, and greater load-carrying capacity than polyester urethane foam.

A polyether-based resin and catalyst system has been developed (Chase Chemical Corp., Pittsburgh, Pa.) to produce low-density flexible polyurethane foams. The system produces foams that set and are tack-free 5 min. after pouring and cure in 10 min. without the use of heat or pressure. The company states that both resin and catalyst are stable and have good shelf life and can be used without modification as they are shipped to the fabricator.

Fashionable belts and handbags are created by electronically heat-sealing sheets of vinyl foam to vinyl sheeting. Heat-sealing is also used to give the finished products a three-dimensional quilted effect. (Photo, Elastomer Chemical)

is said to have taken a permanent set. Similarly, a cushion that becomes softer after constant flexing is said to have suffered a loss of compression or load-carrying ability. On the basis of actual service tests, OFVF has been found to be outstanding on both these counts. Long-term service tests of OFVF indicate that it takes less permanent set than foam rubber. (However, available test methods, which unfortunately are not adequate for evaluating a thermoplastic material, indicate vinyl foam to be somewhat inferior in this regard.) OFVF, since it is thermoplastic, also exhibits temporary differences in hardness or load-carrying under varying temperature conditions, but formulations can be adjusted so that comparatively flat temperature-hardness curves may be obtained, making the differences in hardness noticeable only under conditions of extreme temperature variation.

Another important property of OFVF is the ease with which it can be reshaped and, if desired, bonded to other materials by using various electronic heat-sealing, embossing, printing, and hot-wire cutting techniques.

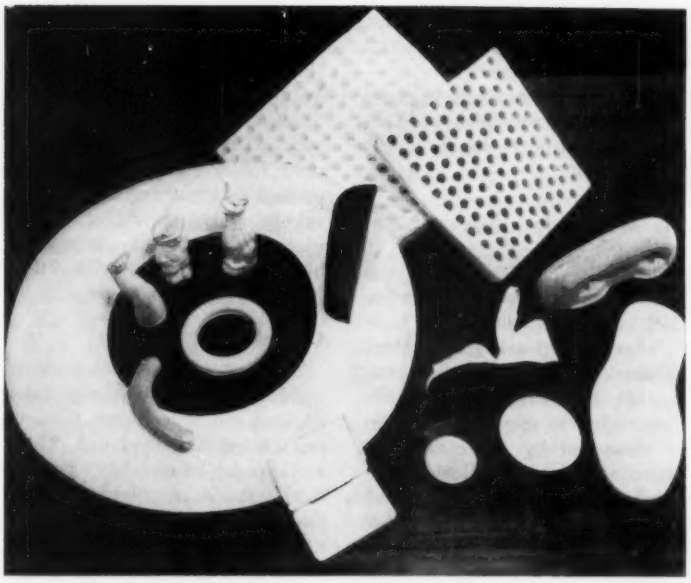
All vinyl foam must be properly fused in order to secure optimum properties. Once properly fused, however, its over-all aging and strength characteristics are excellent. Vinyl foam will not oxidize, dry out, or harden. It is not subject to hydrolysis even under moisture conditions of 100% humidity for extensive periods at elevated temperatures. It is highly resistant to most inorganic acids, alkalies, oils, greases, aliphatic hydrocarbons, and alcohols. Of major importance for many nonseating consumer applications, where one or more surfaces of the foam are exposed, is vinyl foam's color fastness. It can be made in fade-proof white or colors.

OFVF is almost as versatile from a fabricating standpoint as it is from a compounding standpoint. Five different techniques for the production of OFVF products are already a commercial reality and several other techniques are now in the pilot-plant or experimental stage. Included in the first group of current techniques and fields of application are: 1) cored and contoured molded cushions; 2) molded products with integral skins; 3) slab or sheet applications in transportation seating and furniture; 4) electronically heat-sealed vinyl foam slab for a variety of consumer products; and 5) electronically heat-sealed laminated structures for furniture upholstery. Techniques that are under consideration, but not yet commercialized, include extrusion, direct application of foam as a backing to other materials, and adhesive or heat-type laminations.

Jump seat pads for taxicabs are molded of vinyl foam so that each piece has its own skin integral with the foam beneath it. (Photo, Elastomer)

End-uses

Cored and contoured molded cushions: This is the most familiar and well-established type of foam cushioning product. Such cushions are made in lightweight aluminum molds. The internal surfaces of these molds are shaped to provide the necessary contour and edge radii. In addition, the weight-resilience relationship can be effectively controlled by a multiplicity of core holes which are formed by hollow pins attached to the mold cover plate.



Molded products with integral skins: The molds for products of this type can be contoured and cored as above, but also have one additional important characteristic. A design is cast or formed into one or more of the interior mold surfaces. Then, by spraying, slush molding, or brushing an unexpanded plastisol against the preheated mold surface, an unexpanded skin is formed with the desired surface design. Thereafter, the foam is flowed or sprayed into the mold, and after the mold cover (which, if prime-coated, adheres to the foam and serves as a mounting plate) is positioned, the entire assembly is cured and subsequently cooled and stripped as a unit. The resulting product has its own skin which is not only integral with

foam beneath it, but which also has the desired surface pattern and color. Thus, the laborious hand upholstery operation can be eliminated.

Slab or sheet applications in transportation seating and furniture: Where maximum cushioning properties are desired for cushioning furniture and transportation seating, and where design does not permit use of thick foam cushions, vinyl foam has been found to be particularly effective. In addition to the resilience and comfort requirement, vinyl foam in this case meets the additional important requirement of fire resistance.

Electronically heat-sealed products: By using electronic-sealing instead of the previously required molding, die-cutting, and sewing techniques, OFVF can be economically adapted to a variety of consumer products. OFVF is furnished to the heat-sealer in slab or roll sheet form in any desired thickness and in a wide variety of attractive colors. The only fixed investment involved is a properly shielded electronic heat-sealing press and an air compressor or air line connection. The dies used in these machines are extremely inexpensive, ranging from as low as $50 to several hundred dollars, depending upon their size, number of cavities, and complexity. The combination of machine, dies, jigs, and material can be used to form many special shapes such as sponges, brushes, sun visors, arm rests, and many other products and components. Quite frequently the technique is used to make a product consisting of vinyl foam which is sealed to vinyl film or fabrics on either one or both surfaces. "Tear-seal" dies may also be used to obviate subsequent die-cutting or hand-trimming operations.

Electronically heat-sealed laminated structures: While small semi-automatic presses are adequate for fabricating the products discussed above, larger capacity and more fully automated quilting machines must be used for turning out full widths and rolls of sandwich-type laminated materials. The most successful product of this type is composed of a top surface of vinyl-coated fabric, an inner cushioning layer of OFVF in the desired thickness, and a backup layer of a heavy duck fabric. This construction has been widely used in the furniture and automotive upholstery fields. Another combination consists of a satin-surface fabric layer and a vinyl foam backing.

Typical applications for the various types of closed-cell vinyl foams include flotation equipment (buoys, floats, life belts, etc.), outer shoe soles, slippers, and molded and contoured seat cushions. (Photo, Foam King)

(Closed Cell)

BY H. DASH*

Closed-cell vinyl foam is available in both rigid and flexible form and is produced by either of two processes: high-pressure or atmospheric blowing.

In the high-pressure method, a plastisol containing a chemical blowing agent is poured into a steel mold flush with the top edge. The mold is covered with a top plate and gasketed with soft aluminum sheeting. External pressure on the top plate is maintained by hydraulic pressure. Internal pressures developed depend on cavity volume and on the concentration of blowing agent in the plastisol. The temperature of the mold is rapidly brought to the fusion point of the plastisol. At this temperature, the gas is also released from the blowing agent. Because of the high pressures developed, the released gas remains dissolved or dispersed in the fused plastic mass. The latter is cooled in the mold prior to removal. Expansion is achieved by reheating (at about 200° F.) the fused plastic until equilibrium with atmospheric pressure is reached.

The atmospheric-pressure method makes it possible for the material to be produced as slab stock of unlimited size on a continuous conveyor system and without the need for pressurized equipment. In the atmospherically blown method, a vinyl plastisol containing a chemical blowing agent is also used. However, in this method, the plastic mass is fully expanded prior to complete fusion. In thick sections (over 2 in.), optimum internal curing is accomplished by dielectric heating.

Applications of closed-cell vinyl foam include flotation equipment (buoys, floats, life belts, etc.), Arctic clothing, outer shoe soles, thermal and acoustical insulation, gasketing, etc. Outstanding properties of closed-cell vinyl foams are low water absorption, good aging and weathering characteristics, and low thermal conductivity coefficient. Other properties: dimensional stability—up to 2½%

* Technical Director, Foam King, Inc., 1816 Boston Rd., New York 60, N. Y.

linear change after heating 24 hr. at 158° F.; dielectric constant—1.2 at 10^6 cycles; dissipation factor—0.2 at 10^6 cycles; resistant to many acids, alkalies, and alcohols, moderately resistant to aromatic chemicals.

Techniques

BY PETER S. WEILL*

Expanded polyvinyl chloride falls into two classifications: unicellular (closed-cells) and interconnecting (open-cells). The percentage of closed or open cells present in the foam product can be measured by immersing the expanded polyvinyl chloride material in water under vacuum and determining the amount of water that is absorbed (ASTM D-1056-54T).

Several techniques are used to produce expanded vinyls. The first involves the use of chemical blowing agents. The products in this case are generally called *sponges*. Both open-cell and closed-cell expanded vinyl can be produced by this method. The second technique consists of the incorporation of an inert gas in a plastisol by dispersion or solution, and the product is called *foam*.

The more important blowing agents used in expanded vinyl processes are nitrogen-producing compounds. The mechanism of the release of gas is generally one of chemical decomposition caused by heat, which evolves gas and forms thousands of tiny bubbles in the vinyl. Two main processes are used for the production of expanded vinyls with blowing agents: closed blow (for unicellular products) and atmospheric blow (for products with interconnecting-cell structure).

* Marvinol Development Engineer, Naugatuck Chemical, Div., United States Rubber Co., Naugatuck, Conn.

Closed blow

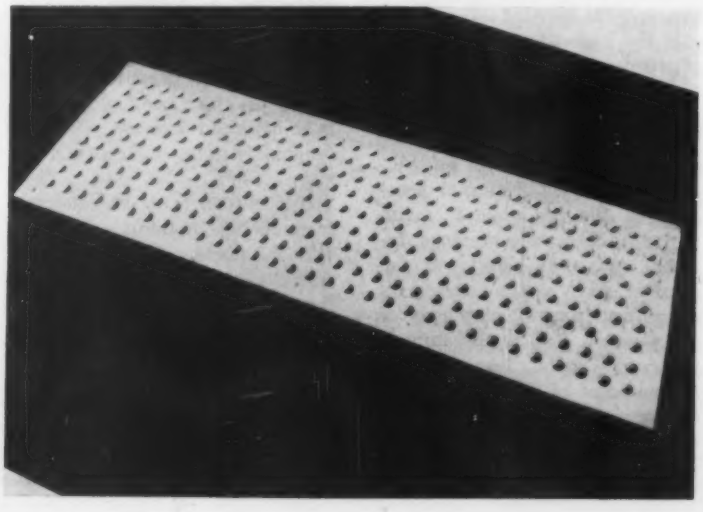
The first process uses a closed mold in which relatively thick sections of unicellular (closed-cell) vinyl are produced. These sections can be sliced to whatever thickness is required. In the closed mold technique, the molded articles retain the details and proportions of the mold, even though the expansion is completed outside the mold.

Extreme caution should be taken when blowing in a closed mold since very high pressures can be developed when the blowing agent decomposes. The mold should be made from sturdily constructed metal in order to withstand the high pressure developed by the blowing agent. A safety factor, covering the possibility of added pressure from vinyl breakdown through an improperly stabilized system, must also be taken into account when using this technique.

The recipe used in preparing closed-cell vinyl sponge varies to some degree, depending upon end-use requirements. In general the recipes consist of vinyl resin, plasticizers, a chemical blowing agent, and stabilizers. A starting point recipe is:

Marvinol VR-10	100.0
Di-2-ethylhexyl phthalate (DOP)	130.0
Barium-cadmium stabilizer (Advance BC-105)	3.5
Celogen	12.5
Celogen AZ	12.5
	258.5

Densities of 4 to 6 lb./cu. ft. are obtained with this formulation. A formulation such as shown above may be prepared with all the ingredients ground on a paint mill. The mold is then filled with the paste and clamped in a steam-heated press. A typical cycle for a 1-in. thick frame is 15 to 25 min. at 320 to 350° F. This is an average cycle and will vary with the formulation. For a ½-in. frame, the same temperature is used but the cycle is cut approximately in half. Mold heat capacities and the method of heating will, of course, determine the variation in the fusion cycle. In general, however, it is advisable to obtain uniform fusion throughout the plastic matrix before decomposition of the blowing agent takes place.



Following the fusion and blowing steps, the closed mold should be cooled. The center of the plastic mass should be well below 200° F. before the mold is opened; otherwise, the stock will be so soft that there is a chance it will rupture.

When the piece is released from the mold, it will be partially expanded. It may then be brought to its maximum expanded size by heating for approximately 1 hr. at 215 to 220° F. in an air-circulating oven. Annealing, which is generally beneficial to the dimensional stability of the finished expanded piece, may be done by subjecting the piece to temperatures of 130 to 150° F. for several hours.

Atmospheric blow

The second method of producing expanded vinyl by the use of blowing agents is called the "free

Developments in molding techniques have made it possible to turn out contoured, cored subway seat cushions of open-cell vinyl foam. (Photo, Elastomer)

blow." This method involves casting on an open mold or coating a suitable web with vinyl dispersion in which a blowing agent has been mixed. The vinyl material is then fused at oven temperatures of 330 to 400° F. and allowed to expand at atmospheric pressure. Free blow expanded vinyl generally contains some interconnecting cells, although 100% unicellular foams are possible.

Plastisol for this method may also be stirred in or ground on a paint mill, but the formulation is slightly altered from the one offered in the closed blow technique. A solvating type of plasticizer is generally necessary to insure fast fusion. The blowing agent content is usually much less than the amount used in the closed blow method. A starting point recipe would be as follows:

Marvinol VR-50 or VR-51	100.0
Diisooctyl phthalate	100.0
Diethylene glycol dibenzoate	20.0
Dythal	3.0
Celogen AZ	0.5— 1.5
	223.5—224.5

Densities of 15 to 20 lb./cu. ft. are normally obtained with this formulation. Open-cell chemical blown vinyl is used extensively as thermal insulation in slush molded plastisol footwear.

Mechanical blow

The second major technique of expanding vinyl is based on the incorporation of an inert gas in a plastisol by mechanical action or by solution in the plasticizer. This product is called vinyl *foam*. A process patented by the Elastomer Chemical Corp. utilizes this technique for making interconnecting-cell vinyl foam. With this process, a wide range of cell structure, resilience, low-temperature flexibility, and load-carrying properties can be obtained. In the Elastomer process the liquid vinyl plastisol is thoroughly mixed with an inert gas, such as carbon dioxide, or nitrogen, at a pressure of 300 to 500 p.s.i. A means of cooling is provided during the agitation in order to increase the solubility of the inert gas in the plastisol. The foamed plastisol, the appearance of which is like whipped cream, is released through a nozzle into a mold, or deposited on a moving forming belt, and leveled by a doctor blade before passing through a dielectric heating unit where it is gelled and fused.

A typical rate of production that has been quoted for vinyl foam slab, 2 in. thick, is 400 lb./hr. on a conveyer speed of 1½ ft./minute. The finished foam is cut and split to the desired size of stock and wound on rollers for storage. By the use of the Elastomer method, continuous production of open-cell vinyl foam, in the density range of 5 to 7 lb./cu. ft., is commercially practical. Sheet stock is now available 60 in. wide up to 4 in. thick.

The Fay Foamer Process, developed by Dennis Chemical Co., utilizes the solubility of the CO_2 gas and incorporates it in the plastisol in a counter-current absorption column. Plastisol is pumped into the top of the tower and allowed to trickle down over packing. CO_2 is introduced into the tower under the packing and moves upward until dissolved in the plastisol. The pressure (below 100 p.s.i.) maintained in the column controls the density of the vinyl foam. For low-density vinyl foam production, a two-stage absorption unit is recommended. The foamed plastisol is then applied and fused in the same manner as described in the previous paragraph.

Mechanically blown vinyl foam can readily be compounded to fire retardancy. The open-cell structure of vinyl foam "breathes" and therefore has found considerable use in the cushioning field.

FOAMED POLYURETHANES

Applications

BY W. W. MARSHALL*

The polyurethane foams are cellular materials prepared by the reaction of polyisocyanates, polyester or polyether resins, and water. The significant feature of this system is the reaction of the polyisocyanate with water to liberate carbon dioxide while simultaneously polymerizing and cross-linking the resin to entrap the liberated carbon dioxide. The density of the foams is therefore controlled by the amount of water and excess polyisocyanate used in the formulation.

The urethane foams can be foamed in place and are self-cured by the exothermic heat generated in the foaming reaction. They can be formulated to have a wide range of physical properties, e.g., densities ranging from 1 to 40 lb./cu. ft., and can be made flame-resistant. The three general foam classifications are: flexible, semirigid, and rigid. Each type is produced by a specific resin or mixture of resins with the polyisocyanate.

Raw materials

Due to the economics involved, tolylene diisocyanate is most often used in production of foams. Three types are available commercially (pure 2,4-tolylene di-

isocyanate, the 80/20 ratio of 2,4 and 2,6 isomers, and the 65/35 ratio of isomers), of which one or more of the isomer combinations can be used in production of foam. However, the least expensive 80/20 isomer ratio is used most often.

A variety of compounds containing two or more active hydrogen groups, e.g., hydroxyl and carboxyl groups, may be reacted with the diisocyanate to produce foams. Polyesters of moderate molecular weight (1000 to 2500), which terminate principally in hydroxyl groups, are most widely used on a commercial scale. The polyesters vary in degree of branching, with the linear polyesters used for flexible foam and highly branched polyesters used in rigid foams. Several commercial polyesters are listed in Table I, p. 339, relating the polyester to the type foam produced.

In addition to the polyesters, a number of other polyfunctional materials, such as castor oils, glycols, drying oils, and polyethers, have been used to prepare foam. Most promising of these are the polyethers which have been used to prepare flexible foams with excellent properties.

Tertiary amines are most often used to catalyze and control the reaction rates. Typical catalysts are N-methyl-, N-ethyl-, and N-coco-morpholine, as well as triethyl-dimethylcyclohexyl [illegible] diethylethanolamine. Emulsifiers are often used in the formulations to assist in dispersing the reactants and water (which acts as the blowing agent) in the mixing operation.

Flexible foam

These foams have a predominantly open-cell structure and are available in density ranges from 1.5 to 6.0 lb./cu. foot. The unique physical and chemical properties (Table II, left), such as high strength/density ratios, high abrasion resistance, resistance to oxidation, oil, mildew, fungi, and vermin, have afforded it acceptance in a variety of applications. The foams are odorless, nonallergic, and may be washed or dry cleaned. They can be sewn or fabricated with available machinery and are made in a wide range of colors.

Advances in this field have been made in the development of polyether foams. These are softer and more resilient, and have greater resistance to accelerated hydrolysis conditions and better moldability than the conventional polyester-type foam.

Generally, the flexible foams are finding increasingly wide usage as clothing innerliners, shoulder pads, carpet underlay, cushions (furniture and airplanes), mattresses, topper pads, acoustical tile, packaging, paint and wax applicators, and many other applications.

Rigid foams

Available in a density range of 1 to 40 lb./cu. ft., these foams are mostly used in applications that utilize their ability to be foamed in place along with their structural and adhesive strength, as well as high impact and vibration resistance. Because of the unicellular structure, rigid foams are excellent thermal insulators, in addition to having high oil and solvent resistance and low water permeability. The maximum use temperature is high and depends entirely on the specific end-use requirements. (See Table III, left.)

Materials for producing rigid foams are also marketed as a two-component package system which enables fabricators to foam in

place by simply mixing the two prepared components and pouring them into the form or mold to be filled. This system is especially useful for filling small voids where full-scale machinery is not warranted.

A growing number of commercial uses have been found for the rigid foams in construction materials, airplane wings and ailerons, vacuum bottles and jugs, radar domes, automobile heater housings, railroad refrigerator cars, and refrigerator trucks.

Semirigid foams

Because of their high impact-absorption properties, these foams are used in the production of automobile crash pads, arm rests, and visors. The crash pads are made by fitting a vacuum formed polyvinyl skin into a mold and then pouring the urethane foam mixture into the cavity. Other applications are in shoe innersoles and athletic padding.

Techniques

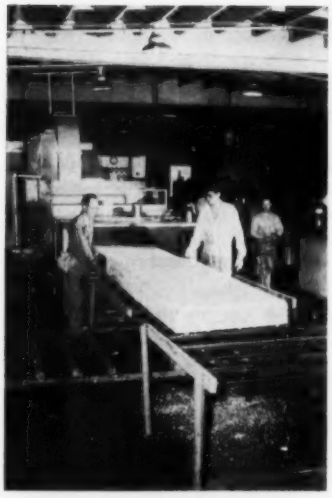
BY HARRY GERSTIN*

During 1956, production of polyurethane foams—both rigid and flexible types—soared to an estimated 30,000,000 pounds. Responsible for this amazing increase has been the development and perfection of not only the basic chemical components, but of mass production techniques and machinery as well. With these major hurdles out of the way, almost unlimited vistas of application have opened up. By 1960, it is estimated that some 75,000,000 lb. of the foam may be produced.

Types of foams

As a prerequisite to the understanding of production techniques, it might be well first to review the varieties of polyurethane foaming materials available to manufacturers.

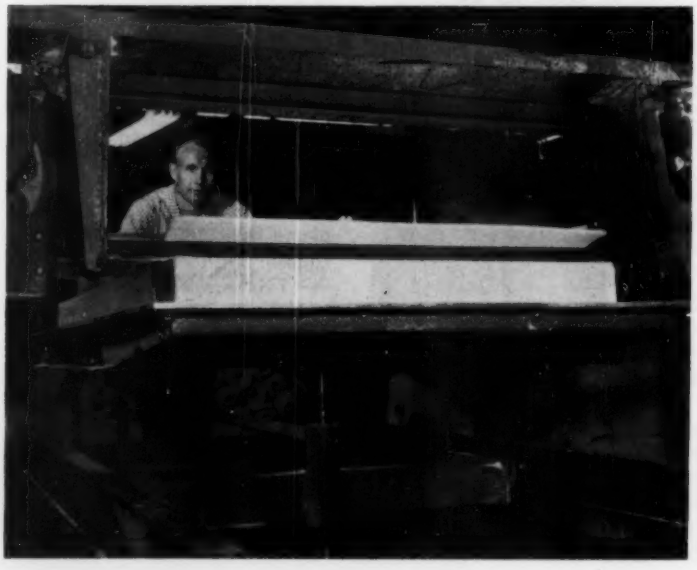
Polyurethane foams are produced in two basic types—flexible and rigid. They are available in densities ranging from 1.5 lb./cu. ft. to more than 70 lb./cu. foot. Cell structure diameter varies from microscopic to about ½ inch. They adhere strongly to any surface free from wax or oils. More stable physical properties are achieved with heat curing.



In addition to the obvious differences in rigidity, rigid polyurethane differs from the flexible type in the manner of manufacture. The rigid type is foamed in place simply by mixing two liquids together, then pouring the mixture into a mold at about the time foaming action begins. The rigid type is seldom foamed into slabs and then fabricated—the method by which the bulk of flexible polyurethanes are made.

Mixing of the flexible type involves a far more complicated technique. Depending upon the formulations, temperature, mixing speeds, and other factors involved, flexible polyurethane can be combined to create structures with light cell walls and large cell diameter, heavy cell walls and large cell diameter, light cell walls and small cell diameter, and many other variations. Truck seating may require one special set of physical characteristics, while vibration-damping pads may require an entirely different set.

Factors in production



Before any production is attempted, the requirements of the application must be studied and the production process adjusted accordingly. Of course, there are certain standard formulations that may fit a wide variety of applications, but when mass production of the material is planned for a specific use, efficiency and economy call for a thorough study of the requirements.

Although the physical properties of polyurethane are depend-

Slab of flexible polyurethane foam emerges continuously from mouth of automatic foaming unit. (Photo, American Latex)

Band saw is all that is needed to cut polyurethane foam to thicknesses as fine as 1/16 inch. In thicknesses of ⅛ in., polyurethane foam has same insulating properties as ½ in. of cotton and wool felt. (Photo, American Latex)

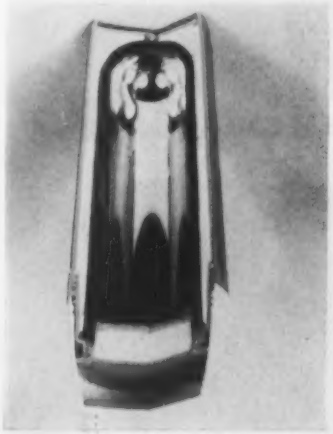
ent primarily on the chemical compounds, the production man is equally concerned with their mechanical combination. This includes chemical proportions, mixing rates and techniques, temperature control, mold configuration, and similar factors. Each of these is not only highly critical in itself, but has an extremely delicate relationship with the others. Thus, to produce competitively priced material, production personnel must fully understand both the chemical and mechanical processes involved.

Controlling reactions

Basically, polyurethane is formed by the reaction of a diisocyanate and polyfunctional reactive hydrogen compounds.

Key to production of rigid polyurethane foam is the formation of the CO_2 which creates the foam. Carbon dioxide must be liberated in a linear manner and at such a rate that the gas is entrapped by the matrix of the material as it commences to gel, thus producing a unicellular structure. If the rate is too fast, the material will not be able to support itself, CO_2 will escape, and the foam will collapse.

To produce flexible polyurethane, gelation is regulated so that the gas is permitted to break through the cell walls at the instant when the walls have become self-supporting, but not yet able to prevent the passage of CO_2.



In the mass production of flexible polyurethane these considerations are achieved by the precise regulation of several factors. First, the temperature of the various compounds must be maintained at a constant level. These compounds are then fed into a mixing chamber by pumps capable of constantly metering the flow at a predetermined rate and pressure. The mixing head must be designed to permit a wide variety of mixing speeds at various viscosities and pressures, so that the material can be ejected at the right moment during the chemical reaction. Nozzle orifice dimensions for each formulation must be carefully controlled and mixing head drive speeds must be regulated to ± 2 to 5 r.p.m. Imperfect design of any of this equipment will result in imperfect "blows" involving variable cell size, fluctuations in density, collapse, "blow holes," and curing difficulties.

Once the material has left the mixing head, it is affected by other conditions which must be correctly controlled before a perfect blow is achieved. The temperature of the mold is critical for some formulations.

Rigid foams also are susceptible to variations in temperature. Unless the temperature follows the exothermic reaction of the formulation, density may vary as much as 25%, or the blow may even collapse. This temperature must be experimentally determined for each new formulation.

Polyurethane foam lining (see cross-section, below) for new vacuum bottle (above) is designed to take advantage of the insulating qualities of the material. (Photo, Du Pont)

Foamed polyurethane crash helmet lining is removed from aluminum mold prior to being placed in infra-red oven for cure. (Photo, American Latex)

Mold design

The configuration of the mold or blow pan is yet another factor that affects the material. Where the cross-section of the mold is relatively small and there is considerable friction between the mold walls and the foaming material, a much higher density may be obtained at the extremities of the blow than at the center, and heavy skins may be formed. This is explained by the fact that, since the material itself is an excellent insulator, the exothermic action of foaming is contained in the center of the blow, but is conducted away by a thin-walled mold. Conversely, there is less drag and lighter densities created at the edge of a blow in a thick-walled mold.

After the polyurethane has foamed, a proper heat cure is necessary to assist molecular cross-linkage and create a fibrous type of foam with excellent properties. *If the material is to be used at elevated temperatures, the cure temperature must exceed the maximum temperature expected in its application.* Finally, the mold must be cooled before removal of the foam to prevent distortion of the final product.

Both rigid and flexible polyurethanes can be easily fabricated by sawing, slicing, grinding, drilling, or by using any of the techniques common to woodworking, including gluing. It can be colored in the manufacturing process with commercially available dyes and pigments.

Production of polyurethane

foam requires careful safety procedures. Vapors generated during the blowing stage are somewhat toxic. Injurious amounts of gas can be produced even by small amounts of spillage. Adequate ventilation is required.

As a safety measure, it is recommended that each man scheduled to work the polyurethane production line be required to undergo a complete physical examination and blood check beforehand and every 90 days during the period that he works in the area.

Production equipment

One of the most important developments in the field has been the design of suitable machinery for the continuous production of urethane foam. Basically, these machines consist of accurate proportioning pumps which feed the raw materials into a mixing chamber. From the chamber, the ingredients are forced through a nozzle into a pan or mold where the foaming and curing reactions occur. To produce continuous slabs (in dimensions that can go as high as 80 in. wide and 11 in. high), the mixing chamber and nozzle are mounted on a track so that the curing pans or molds may be passed beneath it on a conveyor. The length of the conveyor is such as to permit the foaming action to be completed and the foam to cure sufficiently so that it may be handled.

More recently, a portable (3 by 5 by 4 ft.) self-contained, fully-automatic polyurethane foam production unit has been placed on the market. Another portable model is also available to permit foamed-in-place work within a radius of 20 feet.

These machines meter polyurethane component ratios to within 1 g. of predicted density at a normal production of from 5 to 25 lb./minute. Adjustments incorporated into their design will permit standardization of almost infinite variations of density and elasticity.

One unit features a central control panel enabling a semi-skilled operator to start the machine, adjust all necessary pressures, temperature, and flow without the need to make internal adjustments. The operator adjusts for desired temperature, sets the pumps in motion, and first allows one component to flow through the mixing unit for the purpose of calibrating volume. After calibration, the flow of other components is adjusted until all are at the desired ratio.

CELLULAR CELLULOSE ACETATE

BY DR. P. J. WITTE*

Applications

Expanded cellulose acetate, known to industry as cellular cellulose acetate (CCA) or Strux, is a unicellular product produced by a continuous extrusion process wherein cellulose acetate flake is converted to a rigid foam by the flash vaporization of volatile solvent.

Density of the product is a function of both feed composition and operating conditions in the extruder. Foam in the density range of 6 to 7 lb./cu. ft. is presently available, in boards or rods.

A rather dense, smooth skin is present along the entire surface of the product as extruded. Immediately after extrusion the product passes through a pair of parallel circular saws where the edge surfaces are removed and width dimension is established. Removal of all skin results in a decrease in over-all density of about 1 lb./cu. foot.

A distinct advantage of continuous extrusion is that the length of product is unlimited. However, the cross-sectional area is governed by the capacity of the extruder, which, at present, is 6 sq. inches.

Conventional sizes are as follows: 1 by 4 in.; ¾ by 6 in.; ½ by 8 in.; 1½ by 3½ in.; 1½ by 4 in. in boards; and 2¼, 2⅜, and 2½ in. diameter rods. Other dimensions and shapes depend on availability of forming dies.

Besides the excellent strength properties shown in Table I, p. 344, Strux is noted for its thermal resistance and stability. For instance, it may be subjected to temperatures as high as 350° F. for extended periods, and up to 380° F. for short periods, without decomposition. Mechanical properties are not greatly affected by temperature change. At —70° F. room temperature values are decreased only 20 percent. The coefficient of linear expansion of 2.5 $\times$ 10^{-5} in./in. for 1° F. and a thermal conductivity of 0.31 B.t.u./hr./ft.^{2}/°F./in. of thickness further indicate good thermal properties. A burning rate of 4.9 in./min. presents the only feature of thermal weakness.

The water absorption of Strux, expressed in terms of reserve buoyancy after complete immersion in water, indicates an initial buoyancy of 55 lb./cu. foot. This value is reduced to 53 lb. after 24-hr. immersion. Four days of subsequent immersion decreases the buoyancy to 52 lb./cu. ft., at which point stabilization is obtained. Drying results in complete recovery.

Cured CCA has no odor. Toxicity has been thoroughly investigated. The basic ingredients themselves are known to be nontoxic. Since there are no volatile or unstable components present, the formation of toxic elements with an increase of temperature, pressure, moisture content, or other influences is impossible.

Strux is used extensively as a core material in sandwich constructions. In other fields, Strux has found acceptance as reinforcement for aircraft control services, radome housing, and filler blocks under fuel cells. As a buoyant material, it is indicated for life floats, buoys, and other flotation devices. Its dielectric qualities make Strux useful in the manufacture of X-ray and electronic equipment. Particularly important applications include ribs, posts, and framing members in shelters, housing units, trailers, and similar large structures.

One of the most extensive uses of CCA is in gun plugs for jet fighters. Since Strux can be machined to extremely close tolerances and has great strength even at high pressures, the plugs stay

in place during flight. When the gun is fired, the plug completely disintegrates, passing through the jet stream without any damage to internal mechanisms of the ship.

Recently, this foam has been utilized in an experimental packaging unit for shipment of antipersonnel mines and detonators. The high shock- and vibration-resistance of Strux allows packaging of these items in the same parcel. Because of these two properties, cellular cellulose acetate also is useful as a protective covering for batteries.

Techniques

Foamed cellular cellulose acetate is easily machined to extremely close tolerances by ordinary woodworking tools such as band- and circular-saws, lathes sanders, jointers, shapers, planers, and centerless grinders. It is important to note that the strengths are maintained throughout these operations even though skin surfaces have been removed.

It is sometimes required in certain applications manually or mechanically to shape Strux sections to a particular contour. Extruded parts have reasonable flexibility in the direction of extrusion and can be formed in large radii and simple curves, especially in thin sections after skin removal. Flexibility can be increased to a degree by subjecting the piece to hot water or steam for short periods. Dry heat is not effective.

As mentioned previously, since the cross-sectional area of cellulose acetate foam is limited, it is necessary to build up sections where larger areas are required.

Simple gluing procedures work well with this material. Fabricators have used polyester and epoxy resins, particularly where vertical surfaces are encountered, utilizing thixotropic or thickened resin mixes which have little tendency to flow or run due to gravity. Also used are phenol-, urea-, and resorcinol-formaldehyde-type adhesives.

Single-component systems such as those offered by the vinyl- and rubber-base cements are more satisfactory on small-scale operations. Besides elimination of mixing, these types are usually lower in cost and, even more important, have almost unlimited pot life in a sealed container.

One of the most important applications of Strux is in the field of sandwich construction. Because of its high heat-resistance, its high strength-low weight ratio, and ease of bonding, it is well-suited for production of laminates using glass cloth, glass mat, metal, or wood in combination with polyester and epoxy resins. This can be done either by primary or secondary bonding. In primary bonding, the CCA core is merely laid continuously between resin-impregnated facing materials and placed in a press under a pressure of about 30 p.s.i. for 10 min. at 230° F. The resin flows between the individual joints, providing a sound bond and eliminating the need for any preliminary bonding of the CCA sections. Secondary bonding requires roughening the surfaces of the facing material and utilizing the gluing techniques mentioned above.

EXPANDED POLYSTYRENE

BY R. W. THEOBALD*

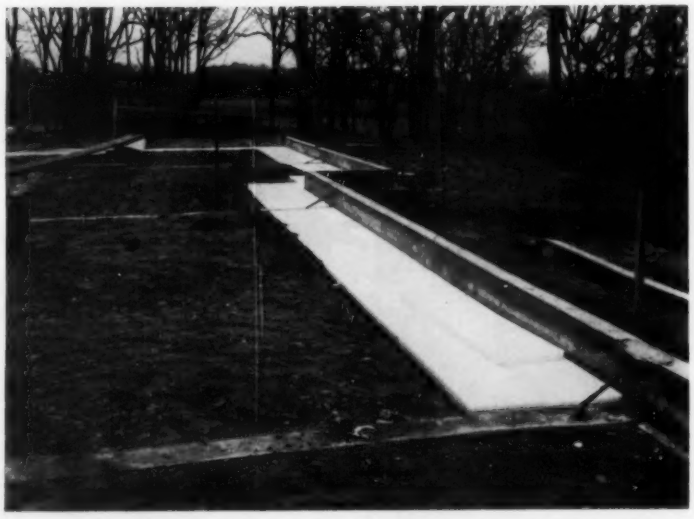
Applications

The fabricator or consumer of expanded polystyrene, made by The Dow Chemical Co. under the trademark Styrofoam, obtains the material in its already expanded form (in blocks, sheets, etc.) and thus he need only concern himself with its fabrication or installation into commercial items. A wide range of properties may be obtained from the various forms of expanded polystyrene and a large number of end uses are possible through the proper choice of available materials.

Polystyrene foam is presently available to the market in densities of 2.0, 3.0, and 4.5 lb./cu. foot. In addition to this low density, these materials have a closed-cell structure and possess a low thermal conductivity, good moisture resistance, fair structural strength, ease of workability, and no attraction for vermin. Because of these properties, polystyrene foam finds extensive application as temperature insulation, as a core material in sandwich construction, as a buoyancy medium, and in packaging. Its pleasing appearance and ease of fabrication make it an excellent material for various decorative and utilitarian applications in the floral, display, and novelty fields.

Among the attributes of poly-

* Plastics Technical Service, The Dow Chemical Co., Midland, Mich.



styrene foam in low-temperature insulation is a compressive strength high enough to permit the placing of concrete or metal floors directly over the material without additional support. The unicellularity of this polystyrene foam prevents the absorption of water or water vapor and insures against any decrease in insulating efficiency. This fact is of great importance where chilling or freezing temperatures are encountered. It is important, too, where the insulation is to be laid directly in the ground, as in residential perimeter floor slab insulation.

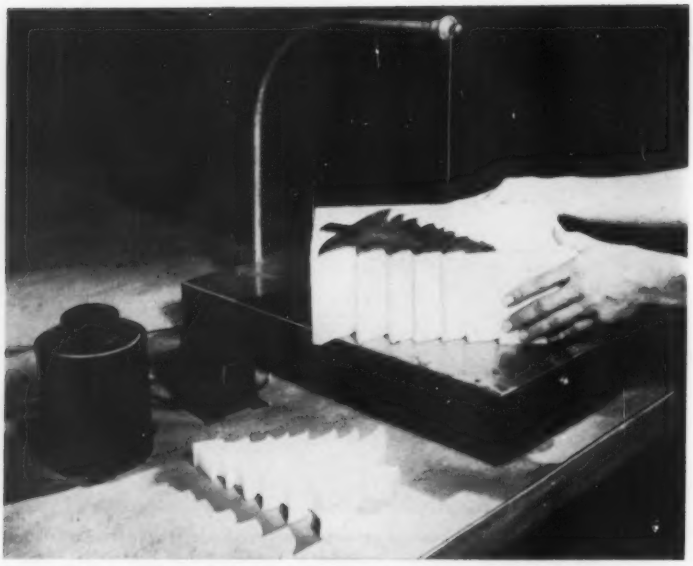
The low thermal conductivity, good structural strength, and rough surface texture of polystyrene foam facilitate its use as a combination insulation and plaster base in residential masonry construction. Direct plastering over the foam is not only feasible but practical, as the surface requires no preparation in order to be able to receive the plaster.

The high shear-strength of polystyrene foam makes it an excellent core material for sandwich panel construction, especially where a lightweight insulating panel is required. Skins for these panels may be of plastic, metal, wood, cement, or any of a variety of other materials and may be bonded on either one of both sides, depending on the use to which the panels will be subjected. These panels have been used successfully in trucks, commercial buildings, schools, and houses as wall and roof panels. Light weight with strength and ease of installation are some of the benefits gained from using panel construction.

Packages and display platforms fabricated from polystyrene foam offer both a pleasing appearance and a measure of protection for the contents. It will absorb considerable shock on impact and can thus be used to protect fragile articles in shipping and warehouse handling. Display bases made of the foam are also attractive for small articles and function as a sales aid to the retailer in his promotions.

Polystyrene foam is used extensively in the field of buoyancy by virtue of its light weight and closed-cell structure. With a buoyancy factor of 55 lb./cu. ft., this foam is being used by boat manufacturers to replace airtight compartments. The use of the foam eliminates the danger of total loss of buoyancy because of puncture or corrosive perforation. The foam is also being used to give buoyancy to life rafts, swimming rafts, aquaplanes and navigation buoys, as well as floating docks.

Low moisture absorption of expanded polystyrene foam is important in use of the material for perimeter insulation of residential floor slab. (Photo, Dow)



The floral field is finding polystyrene foam useful because its cellular structure holds the stems of most flowers firmly in place. Also important in this application is the lightness, ease of fabrication, and inherent attractiveness of the material. The display and novelty field uses the foam extensively for holiday decorations, window and counter displays, carvings, and signs. Colored polystyrene foam is now being produced in red and green primarily for the display and novelty fields, and olive green for the floral market.

Techniques

The lightweight foam produced by expanding polystyrene up to 40 times is available in several forms—standard white Styrofoam 22; a self-extinguishing type known as Styrofoam 33, colored

Curved surfaces, such as in this Christmas tree decoration, can easily be cut in blocks of expanded styrene with an electrically heated wire. (Photo, Dow)

blue for identification purposes; a medium-density foam which weighs approximately 3 lb./cu. ft. and a 4½ lb./cu. ft., high-density material. Also available are foaming-in-place beads which, under heat, can be formed to densities as low as 0.5 lb./cu. foot.

Cutting

Polystyrene foam can be readily cut to desired shapes with conventional hand or power woodworking tools. Power saws, lathes, shapers, and routers may be used to fabricate the foam to various shapes without the use of special techniques. As examples, symmetrical objects may be fabricated by feeding a flat blade having the desired contour into a rotating piece of the foam, or a piece may be hollowed out with a flat blade type of router. Nonsymmetrical pieces are either carved by hand or on a multiple woodcarving machine. In any type of mechanical cutting it is generally most satisfactory to operate the moving part at high speed using a slow feed, thus making many small cuts.

Plain and curved surfaces may be cut with an electrically-heated wire. Fabricating polystyrene foam by hot wire requires more technique than using woodworking equipment, since the cut involves the special skills needed for melting and shrinking of the cell structure.

In using this cutting method, a piece of the foam is fed into a shaped nichrome wire or ribbon that is held at a temperature just below red heat. The amount of power required to heat the wire depends on the rate of cutting and the width of cut desired. At any given wire temperature the width of cut will vary with the rate of feed, i.e., the slower the rate of feed the wider the cut.

Several methods of heating the nichrome wire or tape have proved effective and capable of giving the necessary control. A low-voltage, high-amperage transformer (5 to 10 v., 50 to 100 amp.) or a standard electric arc welder have proved satisfactory. Thin sections of the foam can be die-cut successfully. Either a heated melting-type cutter or a shear-type cutter may be used, depending on the piece being fabricated.

Polystyrene foam can also be cut into intricate designs with various conventional woodworking tools. (Photo, Dow)

Bonding

Polystyrene foam may be successfully bonded to itself and to most other materials, including masonry, wood, cloth, paper, glass, and metal. The rough surface of the foam is ideally suited to mechanical bonding; however, other characteristics such as low melting temperature, susceptibility to strong solvents, and low vapor transmission limit the number and variety of adhesives that may be used.

Drying-type (setting by evaporation of a liquid) adhesives containing active solvents such as aromatic and chlorinated hydrocarbons, ketones, and esters are generally not satisfactory for use with polystyrene foam. These materials are solvents for polystyrene and, upon contact with them, the foam will shrink, soften, and dissolve. Solvent attack is evidenced by an apparent melting or shrinking of the cells.

Adhesives containing nonsolvents for polystyrene such as the lower alcohols and water are satisfactory in applications where the solvent can evaporate. This group includes the many water-dispersed emulsion and latex types of adhesives. Because of the low vapor transmission rate of polystyrene foam these adhesives are generally suited only for bonding the foam to vapor-porous materials, such as wood, masonry, paper, and cloth. However, they can be used on nonporous materials if sufficient open time is allowed to permit the adhesive to dry partially before the bonding surfaces are joined, or where spot or serrated application gives sufficient bond strength. Sections no greater than 2 in. may be bonded without concern when the drying can proceed through the glue line. Adhesives

containing petroleum naphthas as solvents can often be used similarly to adhesives containing non-solvents if caution is observed. These adhesives should be applied to the material to which polystyrene foam is to be bonded and most of the solvent allowed to evaporate before the foam is finally put in place.

Cold-setting types of adhesives that harden and set by a chemical process are generally well-suited for bonding polystyrene foam. It is important, however, to find out by testing whether the adhesive will bond to the material to which the foam is to be adhered. The adhesives in this group include water-reactive materials (portland cement, plaster of paris, etc.) and the types that set by polymerization and/or oxidation (epoxies, phenolics, resorcinols, ureas, and the like). Polyester resins containing styrene monomer are not satisfactory for use with polystyrene foam unless it is very carefully protected against the solvent action of styrene monomer. Hot-melt adhesives, usually asphalt- or wax-based materials, may be used as bonding agents for the foam if they have a workable fluidity at temperatures below 300° F. Polystyrene foam distorts when subjected to prolonged exposure at 175° F. It can, however, be immersed in a molten adhesive for a short period of time, long enough to obtain a coat of the adhesive on the surface. The maximum temperature at which this should be done is 300° F. Hot-melt adhesives usually perform best at the highest permissible temperature. When the temperature is too high, the cells of the foam melt, emitting a crackling sound.

Surfacing and decoration

Many types of surfacing materials can be applied and adhered to polystyrene foam because of its tough surface. Plaster, for example, can be applied directly on the foam. Where reduction of weight is important, a pulp plaster can be applied to provide the required surface. Other types of protective surfacing materials that can be applied successfully to polystyrene foam are the rubber- and asphalt-based water-dispersed weather coatings. Epoxy resins are quite compatible with the foam and form excellent surface coatings. They may be reinforced with glass fibers for added strength.

Polystyrene foam may be painted to practically any desired color. Care should be taken, however, to see that the solvent used in the paint is not one (e.g., aromatic and chlorinated hydrocarbons, ketones, and esters) that attacks polystyrene foam under the conditions of application. In general, paints for use with this foam should be based on film formers that are dispersible or soluble in aliphatic hydrocarbons, alcohol, or water.

All commercial oil paints should be tested for solvent action before being used, since certain of them are thinned with aromatic hydrocarbons which attack polystyrene foam. Even such paints can be applied if care is observed in application. Spraying is the most satisfactory technique for coating the foam, but brushing is often used with good results.

Water-based paints are most successful for applying a colored surface to the foam. The resulting surface, however, is not glossy and two or three coats are sometimes necessary in order to cover all of the surface cells.

Coatings of varying hardness and flexibility may be formulated from alcohol-soluble, film-forming materials such as ethyl cellulose, shellac, and polyvinyl acetate. These coatings provide a tough protective surface and also may be pigmented or dyed to give glassy colored surfaces.

Polystyrene foam can also be colored by using any number of water-soluble or alcohol-soluble dyes.

EXPANDABLE POLYSTYRENE

BY EDWIN A. EDBERG*

Applications

Foam from expandable polystyrene features characteristics which make it useful in diverse fields. Salient properties are closed-cell structure, controllable density, low thermal conductivity (K factor), low water absorption, low water vapor permeability, toughness, excellent dielectric characteristics, and all-around adaptability. Polystyrene foam is dimensionally stable at ambient temperatures to 175°F. It is resistant to acids, alkalies, and the lower alcohols, but susceptible to attack by polystyrene solvents such as ketones, esters, and aromatic hydrocarbons.

Expandable polystyrene foam does not become brittle at low temperatures. Unnotched impact tests on specimens at a density of 4 lb./cu. ft. stored at −100°F. for 48 hr. indicated no loss in impact resistance.

The water absorption of the material is extremely low. The non-interconnecting cell structure prevents the absorption of water into the interior of the molded article by capillarity. The (low) water absorption after 8 days immersion at room temperature is as follows: less than 0.5% by volume and 15.8% by weight (0.0156 lb./sq. ft. of surface area). These values are for foam at a density of 2 lb./cu. ft. and repre-

Contoured platforms of shipper-display package for barber kit are molded of expandable polystyrene. After sale, package can be used as storage box. (Photo, Ambassador Plastics)

* Manager, Dylite Expandable Polystyrene, Market Development, Koppers Co., Inc., Chemical Div., Monaca, Pa.

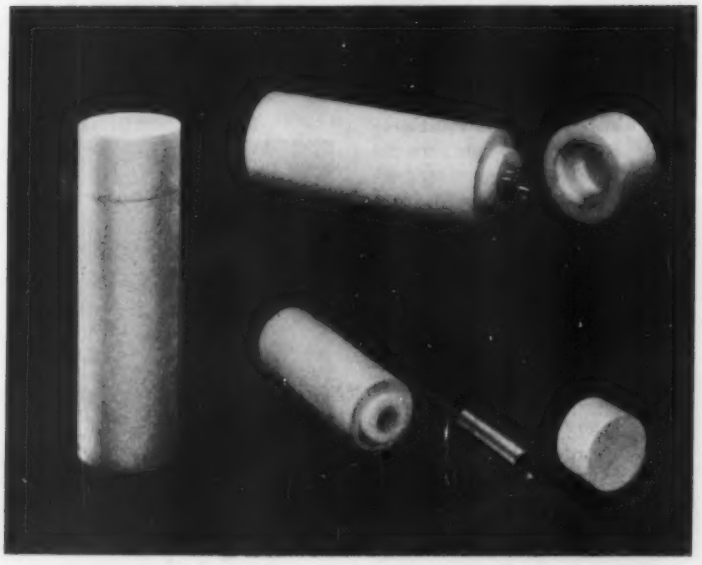
sent maximum water absorption for the material. Higher-density material will show proportionately lower water absorption values. Under a hydrostatic pressure of 10 ft. of water for 48 hr., absorption is less than 1.5% by volume.

The water vapor transmission of the material is also very low. The rate is 0.5 to 1.0 grains/hr./sq. ft./in. of thickness/in. Hg vapor pressure difference, when measured by A.S.T.M. Method D697-42T.

End-uses

Expandable polystyrene's capacity for accurate registration of mold detail led to its early and still-growing use in making toys, novelties, and displays. Silk-screened, dry-colored, and artfully beribboned articles in this category have found popular success and many more markets in the same area remain to be tapped.

Expandable polystyrene has also found a ready market in low-temperature insulation. An excellent low-temperature pipe insulation, for instance, can be produced at low cost by inexpensive molding techniques. Board insulation is finding enthusiastic acceptance for the construction of coolers and freezers. Refrigerator drip trays, freezer evaporators, evaporator supports, and liner shields of expanded polystyrene are being extensively used in the domestic refrigeration industry.



Consumer, industrial, and military packaging problems have been successfully solved with easily-molded, shock-resistant, low-density expanded polystyrene. Its strength, water resistance, and insulating qualities have led to its use for shipping containers for whole blood, plasma, and perishable drugs. Delicate instruments and intricate parts are cushioned against transportation and air-drop shocks by dunnage readily molded from the expandable polystyrene beads.

Foamed polystyrene core boxboard has recently appeared on the market. Greatly increased wet strength, excellent insulation, and enhanced cushioning over conventional material have been obtained from boxes made from the expanded polystyrene board.

Sandwich constructions in which the polystyrene is foamed at controlled densities between sheets of plastic, plywood, and aluminum show promise in the construction field.

Expandable polystyrene also has exceptional buoyancy characteristics, and "in-place" moldings are being used in boats, buoys, etc. to replace air t[illegible]s. Puncturing such molded p[illegible]s will not affect their buoy[illegible]y characteristics.

For protection from damage due to mechanical shock in transit, a container molded of expandable polystyrene is used as the shipper for a vibrating reed. Top of cylinder is easily pulled off (inset). (Photo, Ambassador Plastics)

Techniques

Expandable polystyrene is [illegible]o-duced as free-flowing beads [illegible]n-taining an integral expan[illegible]g agent. When exposed to h[illegible]at, these beads "puff" from a bulk density of approximately 35 lb./cu.ft. to as low as 0.25 lb./cu.foot. The expanded beads show an interesting increase in resilience at very low densities. Moldings have been produced at densities under 0.5 lb./cu.foot.

Foaming expandable polystyrene beads ordinarily comprises two discrete steps: 1) heat pre-expansion of the virgin beads; and 2) further heat expansion of the pre-expanded beads within the shaping confines of a mold.

Extrusion and virgin bead molding are the chief exceptions. In unconfined pre-expansion, the translucent beads assume spherical shape and become white in color. Confined and subjected to heat, either the virgin or pre-expanded beads can produce a smooth-sk[illegible]nned, closed-cell foam of controlled density registering every detail of an intricate mold.

Pre-expansion

To minimize formation of a density gradient and to ensure uniform expansion, expandable polystyrene beads are pre-expanded to the approximate required density.

Batchwise, pre-expansion is suitable for preparing small quantities for experimental purposes if close control of the pre-expanded density is not critical. A common infra-red heat bulb is mounted 4 to 5 in. above a tray and the beads distributed in a thin layer over the bottom of the tray and allowed to expand.

Continuous pre-expansion is presently accomplished by moving belt or disk exposure of the beads to infra-red strip heaters, by screw-fed exposure to hot water, and, most recently, by introduction into a stream of steam and air and subsequent agitation in a closed container.

Oldest and most amenable to

"pre-puff" density control is the method of continuously feeding the expandable polystyrene beads in a monolayer to a conveyor belt passing under a bank of infra-red strip heaters. The lacy network of pre-expanded beads is readily broken up in a breaker at the end of the machine. Bulk densities of 1.5 lb./cu.ft. to 20 or more lb./cu. ft. can be obtained with a commercially available belt pre-expander. Desired densities are obtained by varying belt speed, height of heaters above beads, and electrical input to heaters.

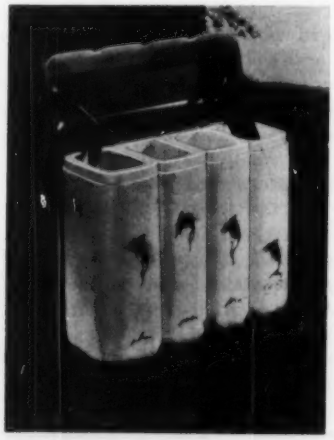
High-volume, low-density (1 lb./cu.ft.) steam pre-expansion equipment has shown considerable promise and will soon be available commercially. Virgin beads are sucked into a steam/air stream and ejected into a suitable receiver equipped with an agitator. Pre-expanded beads emerge continuously from the top of the receiver and are conveyed by air to suitable hopper storage.

Fairly high-volume, low-density pre-expansion has also been achieved by feeding virgin beads into a screw revolving in water above expansion temperature.

Processing

"Expansion" or "molding" of expandable polystyrene beads requires exposing the pre-expanded or virgin beads to heat in a confined space. The confining space may be a mold, a structural form such as a boat hull, or the lips of an extruder die. Heat can be supplied by direct steam introduction, by "in situ" steam formation, and with normal extruder heating equipment.

Relatively simple and inexpensive molds of aluminum, brass, and stainless steel are used. They must be provided with some means of clamping—a light press or "C" clamps will often do. Lands of the molds should not be too well finished, since some roughness of the parting line will permit escape of steam condensate "squeezed" from the molded piece. Hand-filling is satisfactory in many instances, but venturi tube loaders have provided uniform blow-filling in fast cycle production setups.



Where the physical construction and configuration of the cavity permit the use of steam, "foaming in place" can be accomplished. Boat hulls and refrigerator shells lend themselves readily to this treatment.

Extruder dies must be specially designed to control expansion but can be used on conventional plastic extruders.

Expansion techniques

Direct introduction of steam into the mold cavity is the fastest way to accomplish expansion. The latent heat of the steam causes expansion of the beads in a matter of seconds. Three procedures have been developed for introducing steam into mold cavities:

1) Perforated cavity plates backed by suitably-baffled steam chests. Cavity walls should be as thin as consistent with good design practice and the perforations made 1/32-in. in diameter and placed one hole for every 2 sq. in. of surface area. Single and multi-cavity molds of this type in suitable air and hydraulic presses have been used to produce display and packaging pieces, toys, and refrigerator components. Expansion times with these molds range from 10 to 90 sec. at from 10 to 40 p.s.i. steam pressures, giving temperatures of 230 to 275° F. Cooling times range between 1 and 5 min., depending on the conformation of the piece and the cooling provisions built into the mold. The molded piece must be cooled below 122° F. before release from the mold to prevent postexpansion.

Carry-all kit for sportsmen is molded of expandable polystyrene. Kit weighs only ½ lb. and will float even when filled. (Photo, Bucks Industries)

2) Small runs of small objects are often made by exposing a filled perforated mold to steam in an autoclave capable of rapid steam pressurization to about 30 p.s.i. A small laboratory autoclave or a sealed-off pipe section can often serve as a pressure vessel for experimental work. Expansion times vary from 2 to 5 min. at operating pressure for small objects, while large ones may require 10 to 15 minutes. Cooling is usually effected by atmospheric cooling, water spray, immersion in water (quench cooling), or some combination of the three.

3) An exceptionally versatile technique for direct introduction of steam into cavities involves use of a simple steam probe. Aluminum, copper, or brass tubes are sealed at one end and attached to a flexible hose or header at the other. Four rows of 1/32-in. diameter holes, spaced 1 to 1½ in. apart at 90° intervals, are normally bored in the tube, although other spacings and row-staggering can often be employed to good effect. The effective steam penetration radius of a single probe is about 6 inches. When more than one is required, probes should be spaced 10 in. apart, except that intricate designs and large-area moldings may require closer and more carefully-planned spacings.

Foaming-in-place is most often accomplished by the probe technique. Large buoyancy members, insulated wall sections, and in-place sandwich structures are common products of this technique. Immediate withdrawal of the probes after 10 to 15 sec. of 20 to 30 p.s.i. steam injection allows the material to close up the probe holes by expansion. Cooling the pieces with probes in place leaves well-defined holes.

Minor techniques for combining probes with headers, flexible hoses, and multiple-outlet, timer-controlled steam chests have been developed and make steam a reliable, all-purpose method of expansion.

Expansion times with steam probes ordinarily range between

10 and 75 sec. and steam pressures between 20 and 40 pounds. Air, water spray, and water immersion cooling can be used. Probes can also be equipped to circulate cooling water through large pieces.

"In situ" steam formation is often used in the experimental phase of a new expandable polystyrene molding project. An inexpensive, unperforated cavity shell is filled with a slurry of beads and water, clamped, and heated in an autoclave or oven. The water generates steam on heating and distributes heat evenly throughout the mold. Polystyrene foam is an excellent heat insulator and only an outer shell would fuse were water not present. This is slower than direct steam introduction, but low cost commends it in experimental work.

Rotating molds, filled with dampened beads, not yet expanded, will produce pieces of exceptionally uniform density because the rotation eliminates the density gradient characteristic of stationary virgin bead moldings.

Extrusion: Conventional extruders with low compression screws and high L/D's are suitable for extruding a special grade of foam through profile dies. Expansion occurs at the die lips, and die profile design requires considerable experimentation. Rods, tubes, and film have been satisfactorily produced.

CELLULAR POLYETHYLENE

BY J. A. SNYDER*

Applications

Cellular polyethylene is, as the name describes, polyethylene containing independent cells of inert gas or air. The number and size of the cells which are in the foam are usually uniform, so that the surface of articles formed from this material is even in texture and pleasant to the eye. Methods of forming vary. The most common is the extrusion process, which produces continuous lengths of varied shapes; the compression molding process is also employed with success; but, although vinyl, phenolic, and rubber foams are produced in large volume by this process, its commercial use is not yet widespread for polyethylene. Injection molding has been accomplished with relatively little commercial success to date.

In the form of extruded rod, disks sliced from rod, and disks stamped from sheeting, cellular polyethylene is used in such minor varied applications as: lightweight spacers, bumpers on small boats, and bottle cap liners. However, the largest application by far today is primary insulation for communication cables: coaxial cables, television lead-in wire, and other high frequency cables. The inherent properties of polyethylene — chemical, moisture, and abrasion resistance plus flexibility and toughness—are adequately retained when polyethylene is foamed. In addition, the capacitance of the foamed insulation is reduced to levels even lower than that of the solid polyethylene. The dielectric constant of the cellular insulation most commonly produced is 1.5 compared to 2.3 for solid polyethylene.

Table I, below, gives some typical values for the physical and electrical properties of cellular versus solid polyethylene.

* Development Dept., Bakelite Co., Div. of Union Carbide Corp., Bound Brook, N. J.

Moisture resistance

For many electrical applications, exposure to moisture is unavoidable. Therefore, to insure continuous and consistent service, the absorption of water by the insulation must be at a minimum. Cellular polyethylene is slightly less resistant to moisture permeation than solid polyethylene of equal thickness. However, due to a balancing of external and internal vapor pressures, cells do not become filled with liquid water, and relatively little water is absorbed. Figures 1 and 2, p. 351, show the dielectric constant and water absorption plotted against water immersion time for solid and cellular polyethylene insulations of similar thickness. A relatively small increase in moisture content during immersion is noted in the cellular insulation during the first 30 days and then no further change is noted through the remainder of the test period of 100 days. No significant change in dielectric constant is observed.

Good moisture resistance and 50% weight reduction have made possible a floating geophysical cable in which the lines are coated with cellular polyethylene. This floating cable permits the usage of more complicated communication systems and greater power consumption at points miles from shore without handling cumbersome equipment.

Foamed polyethylene has been

tested as a thermal insulator. Because of its relatively low melting point, its use must be restricted to applications where temperatures remain under 90° C. Excellent chemical properties indicate cellular polyethylene's possible future use as an insulator for chemical laboratory refrigerators and cold boxes. Figure 3, right, presents the thermal conductivity versus density.

While it is widely used today as a dielectric material in high-frequency cables, foamed polyethylene is still a neophyte in the cellular plastics field. Major economical advantages in weight reduction and an excellent combination of chemical, electrical, and physical properties are expected to create new and even more important uses soon.

Techniques

Cellular polyethylene is produced by the extrusion of a polyethylene compound containing an intimately dispersed chemical blowing agent. Extrusion can be accomplished with conventional equipment.

The correct choice of the blowing agent used in the production of cellular polyethylene for an electrical end-use product is a critical one, and it must meet several unusual requirements. To maintain the inherent electrical properties of the polyethylene, the blowing agent, the gas liberated by it, and any residual products must not absorb moisture and thereby degrade the insulating characteristics of the compound. The blowing agent used should liberate a maximum of gas and leave a minimum of residue. The residue should be nonpolar so that the low-loss characteristics of the polyethylene insulation will not be impaired. In applications where the electrical properties are not of great importance, other parameters for the blowing agent specific to the particular application are essential. For example, in bottle cap liner applications, the blowing agent and its residues must be nontoxic. In decorative sheets, color stability is a must.

Since the blowing agent must liberate gas under controlled

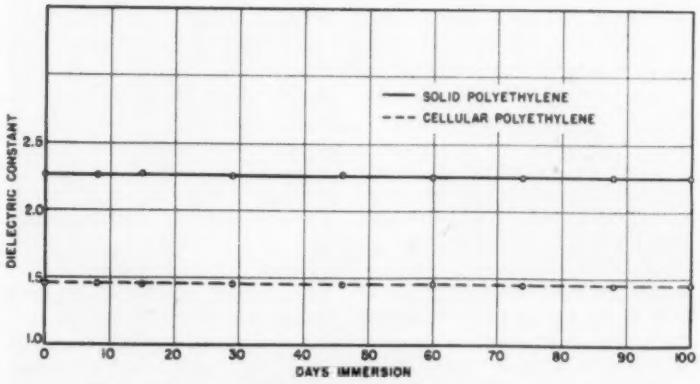

Fig. 1: Dielectric constant plotted against water immersion time for solid polyethylene vs. cellular polyethylene materials

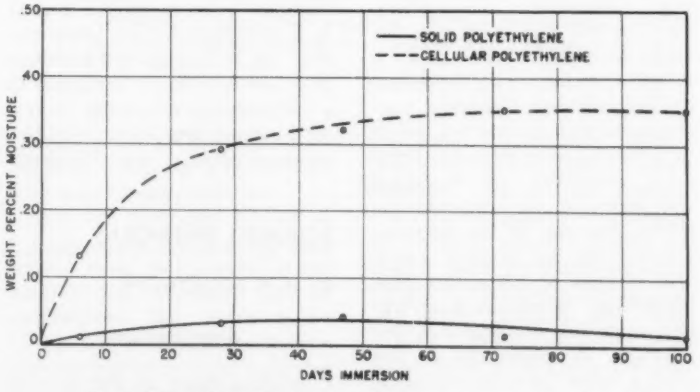

Fig. 2: Water absorption plotted against water immersion time for solid polyethylene vs. cellular polyethylene materials

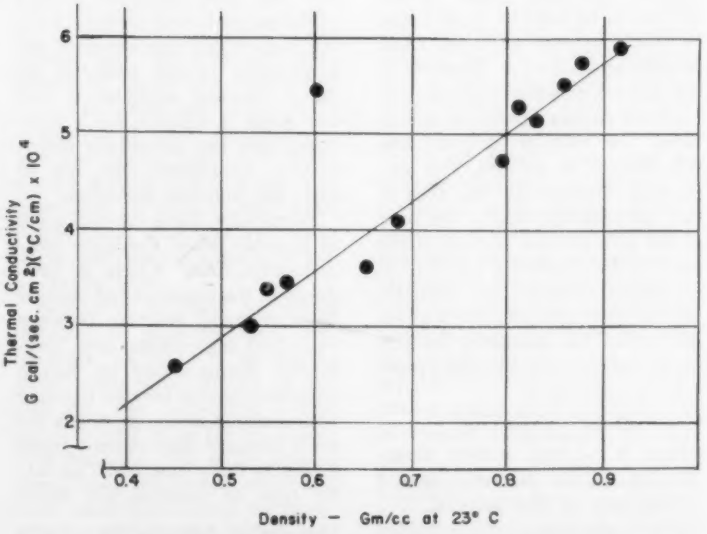

Fig. 3: Chart plotting thermal conductivity of cellular polyethylene vs. density

conditions, extruders that can be regulated both as to heat and pressure appear more adaptable to this critical operation. Aside from the actual extruding operation, the machine used in processing cellular polyethylene must perform two additional functions: 1) by application of heat, the extruder must cause the blowing agent to liberate the gas; 2) by maintaining uniformly high pressure in the barrel, head, and die, the extruder must ensure against premature expansion of the liberated gas before the material emerges from the die. A machine properly adjusted to heat and pressure will give a product with a smooth surface, a unicellular structure, and a uniform bubble size. Operating temperatures that are too high will give less uniform bubble size and a rougher surface with attendant cooling problems. Operating temperatures that are too low result in a high-density material. Optimum conditions for extrusion will vary with the particular extruder, the size of the extruded article, and the blowing agent.

A method of preventing premature gas expansion is to employ a die that develops sufficient pressure. A minimum of 1000 p.s.i. is usual for wire insulation, and pressures of 2000 p.s.i. are more satisfactory. High pressures can be maintained by employing double- or triple-tapered dies to lengthen the over-all die length. The land length of the dies must be kept to a minimum to insure smooth surfaces. Land lengths equal to the diameter of the die are considered maximum.

Under proper operating conditions, the cellular polyethylene will double in volume. This expansion requires that the area of the die opening, minus the area of the wire or core, be 50% of the area of the finished insulation. A convenient formula for computing the final diameter for a given die size or the necessary die size for a specific final circular cross-section diameter is:

$$D = \sqrt{2D_1^2 - d^2}$$

where D = final outside diameter, D_1 = die diameter, and d = diameter of wire or core.

For applications where higher densities are required, cellular stock can be blended with a solid polyethylene compound to achieve the desired density. Higher densities can also be obtained by extruding at reduced temperatures, thus limiting the extent of blowing. However, the results of limited blowing are extremely difficult to reproduce and, in every case, it is recommended that all of the gas be liberated from the blowing agent during the extrusion operation.

Screw temperature control is necessary with the insulation materials extruded today so as not to over-heat the compound. The exact temperature varies with the extruder. Temperatures from 20 to 100° C. have been used successfully. A screw length-to-diameter ratio of 12:1 or higher is more effective than lower ratios, while a high-compression-ratio screw is to be preferred to a low-compression-ratio screw of the same type. Screws of the constant-pitch, variable-depth type, with a three-to-four flight metering section, are found most satisfactory. Preheating of the wire or core to between 212 and 260° F. is desirable for achieving a smooth, regular surface. Lower temperatures tend to give a lumpy material; higher temperatures result in uneven cooling and flattening of the insulation.

While it is possible to use direct water cooling for thin-wall insulation, heavy walls require a long stretch of air cooling. Too rapid quenching of the product will tend to flatten it because of its weakness at the extrusion temperature. Another cause of insulation deformation is the rapid contraction of the occluded gases before the polyethylene has had an opportunity to develop strength. It is possible, however, to minimize these tendencies by using the lowest compound temperatures that will give complete blowing and good forming behavior in the die.

FOAMED PHENOLIC

BY R. P. COURTNEY*

Applications

Phenolics share in the general upsurge of experimentation and testing that has taken place in the field of plastics foams during the past year. One of the major results of this intensive examination has been improved control of the properties of phenolic foam —a feature that has increased the practicality of the material for many existing applications and has made it suitable for a relatively new and potentially large-volume application—the use of foam for building insulation.

Essentially, there are two types of phenolic foam available commercially—foam which is produced in the conventional manner by a chemical reaction between resin and ingredients, and "premixed" foams based on hollow phenolic spheres bonded together with various resins in much the same manner that cement binds gravel to form concrete. This latter type of material, for which the phrase "syntactic foam" has been coined, is unique among plastics foams, since its "foamy," or cellular, character depends on the hollow nature of the spheres, rather than on any chemical reaction.

Reaction-type foams

The reaction-type foam results from a reaction between phenol and formaldehyde (the constituents of a phenolic resin), a catalyst, and certain modifying agents. The prime characteristics of the foam produced are light weight, high stability, heat resistance up to 250° F., and nonflammability. It is also among the most inexpensive of plastics foaming materials. Since a composite structure, about 40 to 60% open and closed cells, is formed during foaming, phenolic foam is a good thermal insulator with some acoustical insulating properties as well.

In practice, phenolic can be foamed to densities ranging from ⅛ lb./cu. ft. all the way up to the density of nonporous resin, which is about 80 lb./cu. foot.

* New Products Engineering Dept., Bakelite Co., Div. of Union Carbide Corp., 30 E. 42 St., New York, N. Y.

Phenolic resin foam of commercial grades has its best thermal insulating value at a density of about 2 lb./cu. foot.

Phenolic foams that are of this density have a "K" value of 0.18 B.t.u./in./ft.^{2}/°F./hour. However a low-density foam does have better insulating properties when mechanically compressed to higher densities. Compressing low-density foam maintains the thin cell walls of such foam, while increasing the number of air cells in an inch of thickness. Thus, more insulating units per inch of thickness are provided, resulting in a lower "K" factor. Since increasing the density, either chemically or mechanically, increases the cost factor, it should be noted that a foam density of ⅓ lb./cu. ft.—which is one that has a "K" factor that is in the order of 0.26 to 0.28—is still within the range of insulation which is provided by the conventional materials.

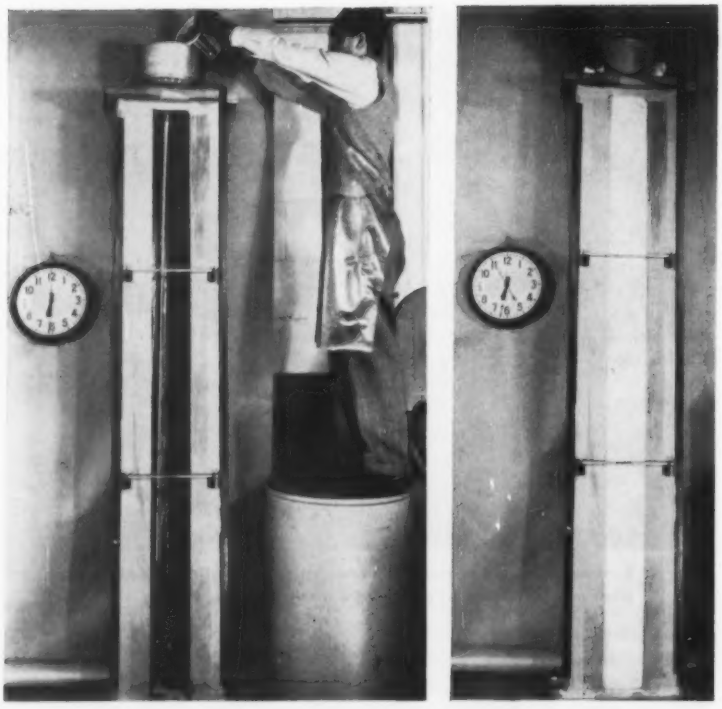
Sandpapered to a fine texture and coated with a pore-sealing solution, phenolic foam may be worked as a handicraft material. (Photo, Bakelite Co.)

Building insulation

The motivating factor encouraging the use of phenolic foam for building insulation has been the successful development of installation techniques that make the best use of the foam's unusual properties. One such technique involves the installation of the foam conventionally by filling wall spaces with precut, factory-produced slabs. A more desirable technique, from the standpoint of economy and speed, is based on foaming the material into horizontal prefabricated panels and structures on a moving conveyor belt. As a result of recent developments, phenolic foam can also be adapted to foaming-in-place operations right on the building site.

Laboratory research has resulted in phenolic resin formulations which will foam in a vertical wall cavity to controlled heights, at whatever insulating density desired, and with uniform density throughout the structure. These properties are controlled by carrying out the reactions at high speed through the use of carefully prepared formulations. As an example of the speeds involved, an 8-ft. wall cavity, about 4.3 cu. ft. in area, is filled in less than 60 seconds. The foam permanently bonds itself to the wall, providing no-sag insulation.

Since the foam does not act as a vapor barrier, a separate material, such as plaster board backed with aluminum foil, or polyethylene film, needs to be added. To handle a continuous foaming operation, special mixing equipment is needed. Equipment of this kind is being made available commercially.



In addition to thermal insulation, reaction-type phenolic foam can also be used as a handicraft material. Formulated to the proper density and strength, foam blocks may be produced with almost no grain. The blocks can be cut smoothly and cleanly with simple hand tools. Sandpapered to a fine texture and coated with a pore-sealing solution, the new foam may be formed into vases, bowls, trays, desk sets, and other items, with an appearance similar to carved stone.

Normally resistant to water penetration, phenolic foam can, however, be made to be readily water absorbent. Blocks of the material, so produced, form highly useful bases for cut flower arrangements. The gaily colored blocks keep the flowers moist and fresh while eliminating the problems of spillage that accompany conventional containers. Water-absorbing foam blocks also make excellent cigar-counter humidifiers. Other specially produced and colored phenolic foams are finding wide acceptance as lightweight decorative material, e.g., in motion picture and stage scenery construction and in retail store window and counter displays.

Syntactic foam

A new concept in foamed plastics was introduced with the development and commercial acceptance of syntactic foam. Hollow, microscopic, phenolic-resin spheres may be bonded together with a polyester, epoxy, or phenolic binder to form a low-density, foam-like material. By choice of binder and, also, by varying the ratio of spheres to binder, a wide range of foam densities can be obtained. One of the more obvious advantages of syntactic foam is that it may be used as a foamed-in-place material without the need for special equipment. Syntactic foam is capable of being utilized in techniques which make possible do-it-yourself applications.[1] The un-

[1] The best sources for information on syntactic foam for do-it-yourself applications are the compounders of this material. Syntactic foam is compounded by: Palmer Products, Inc., Worcester, Pa.; and National Engineering Products, Inc., Washington, D. C.

By carrying out the reactions at high speeds, phenolic resin formulations can be foamed in a vertical wall cavity to controlled heights and with uniform density. As shown above (note clock to left of container), an 8-ft. wall cavity about 4.3 cu. ft. in area can be filled in less than 60 seconds. The foam permanently bonds itself to the wall so it does not sag. (Photo, Bakelite)

cured foam is normally handled as a putty-like mass which can be molded to shape, troweled onto suitable surfaces, forced into cavities, or pressed into sandwich core structures.

The sphere is an ideal engineering structure and the spherical cells of syntactic foam greatly contribute to its strength properties. This spherical cell shape brings to syntactic foam one of the highest strength-to-weight ratios of all plastics foams, along with good insulating qualities. When mixed with the various resin binders, some of which are room-temperature curing, the spheres produce a foam which is also among the most easily handled of plastics foams.

Perhaps the greatest potential for syntactic foam is as a core material in sandwich-type structures. By the use of this controlled-foam technique, flat boards and contoured shapes are produced with equal ease. Syntactic foam materially reduces the flexibility of reinforced plastics with negligible increase in weight. Experimental sandwich structures consisting of cores of phenolic spheres, polyester resin, and loose fibrous glass strands between fibrous glass mats show flexural strengths ranging from 1700 to 4500 p.s.i., tensile strengths between 1600 and 2900 p.s.i., and compressive strengths as high as 12,100 p.s.i.

Syntactic foam is finding expanding use as a core material for such reinforced applications as boat hulls and decks, and reinforced sections of airplane structures.

Syntactic foam also presents a means of applying do-it-yourself techniques to repair of wood structures either in the home or in industry. Rotted-out wood structures can be repaired by troweling the syntactic mixture into the area and letting the putty-like foam cure, or set, until it is hard. The use of epoxy resin —a room-temperature curing material—as the binder in the foam contributes to its ability to cure without special equipment. [illegible]y simple repairs can be eff[illegible]d, and costly structural replace[illegible]ts avoided, with syntactic foam.

Either as a cast materi[illegible] in rotted-out wood structures, [illegible] as a core material in sand[illegible]ich structures, phenolic syn[illegible]tic foam can be easily sawed, pa[illegible]ed, or drilled.

Techniques

Special techniques and formulations have been developed for the foaming of reaction-type phenolic resins and, also, for the preparation of phenolic syntactic foam. In reaction-type phenolic foams, these procedures control the phenol-formaldehyde reaction to yield a uniform, lightweight, resilient material. Syntactic foams which involve no chemical reaction during mixing are prepared by binding together hollow, microscopic phenolic spheres with appropriate formulations either phenolic, epoxy, or polyester resins. Putty-like in consistency, syntactic foams can be used in techniques which make possible do-it-yourself applications. The following suggested formulations and processes have yielded satisfactory results in preparing phenolic foams.

Reaction-type foams

This type foam results from the utilization of the "built-in" heat of reaction of the phenolic resin to cause vaporization of the small amounts of water and solvent present in the mixture of resin and catalyst. During the foaming process, the resin changes rapidly from a free-flowing liquid to an infusible cellular solid. A proper balance of reaction and expansion results in the formation of a foam having a volume as much as 200 times greater than the original liquid resin.

Although the conversion process for making phenolic foam is very simple, involving as it does, the mixing of fluid resin and acid catalyst at room or slightly reduced temperatures, the rapidity of the reaction makes the use of automatic equipment highly desirable, and certain special handling techniques imperative.

In a typical foam formulation, a

wetting agent and isopropyl ether are mixed with the liquid phenolic resins. The isopropyl ether is incorporated into the formulation to yield a finer, better grain in the finished foam. To date, Tween emulsifier No. 40 (Atlas Powder Co.) appears to be the most satisfactory wetting agent.

In actual mixing, the wetting agent is dispersed in the isopropyl ether first and, then, with continuous stirring, this mixture is added to the resin.

A typical catalyst formulation is prepared by adding sulfuric acid very slowly and with continuous stirring, to isopropyl ether. In this operation, the mixing vessel should be immersed in an ice bath or under a reflux condenser.

The temperature should not be allowed to rise over 50° F.

When the sulfuric acid is thoroughly mixed with the isopropyl ether, the catalyst is completed by adding phosphoric acid and thoroughly mixing.

As a cautionary note, it should be realized that these acids are corrosive to skin, metals, woods, etc. Therefore, glass or porcelain vessels should be used and protective goggles or face masks should be worn. Any acid splashed on the skin should be washed away immediately with copious quantities of water. Since the isopropyl ether is highly flammable, as well as somewhat toxic, it should be kept away from sparks and flame; precautions should also be taken so that the user avoids breathing its fumes.

The components are combined and beaten with an agitator. This beating introduces many small air bubbles into the resin. These bubbles serve as "seeds" for the foam formation, and increase the liquid resin volume as much as 20 percent. When the volume of the solution has increased about 20%, the mixture is brought to 77° F., and hardener, also at a temperature of 77° F., is added to the foamable resin.

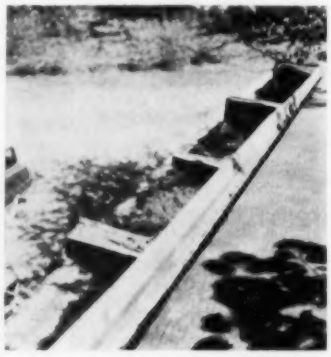
The mixture is then agitated violently with a propeller-type stirrer for 5 sec. and immediately poured into the foaming container. The material will foam in 7 to 8 sec. after adding the hardener.

Catalyst concentration and temperature of ingredients may be varied to influence the speed of the foaming reaction. Higher-density formulations made with blends of phenolic resins react more slowly than do the low-density formulations.

Although phenolic foam can be produced in any container, it is generally advisable to maintain a slight back pressure on the solution during the exothermic reaction. A simple method of obtaining this back pressure is to invert a container of the desired shape over the foaming pan. As the foam expands, the weight of the container provides sufficient back pressure and the foam uniformly fills the container.

Since the entire operation from the introduction of the acid catalyst to the formation of a fully expanded block of low-density foam is completed in about 45 sec., a cycle controller to initiate automatically the various steps in the process, is highly desirable. The use of such automatic features greatly improves efficiency and uniformity in the production of the reaction-type phenolic foam.

Syntactic foam



In practice, syntactics are made by combining hollow, microscopic phenolic spheres with either phenolic, epoxy, or polyester resins in much the same way cement and gravel are mixed to form concrete. When bonded with any of these resins, the phenolic balloons produce a foam-like, low-density, cellular composite. Putty-like in consistency, the uncured syntactic foam hardens into a material of high strength and light weight. Foams varying in density from 10 to 40 lb./cu. ft. can be simply and quickly produced by varying the proportion of resin binder to the phenolic spheres.

The following formulations and procedures are typical of various types of syntactic foams:

(POLYESTER BINDER)

Composition	*Parts by weight*
Polyester resin PLL-5000	50
Phenolic spheres BJO-0930	50
Peroxide catalyst	0.5
Cobalt accelerator	0.5

Procedure: Add a weighed amount of polyester resin to the bowl of a kneader-type mixer. With agitation, add the proper amounts of catalyst and accelerator. (*CAUTION:* It is extremely important that they be added separately since combinations of peroxides and cobalt naphthenate are explosively reactive.) Gradually add the phenolic spheres to the mix. After these are added, continue mixing until the components are well-dispersed. The resulting mixture will be a thick, putty-like mass which then may be placed in a suitable mold and cured at room temperature. Temperatures up to 212° F. can be used to accelerate cure. The above formulation produces a foam which has a density of 10.5 lb./cu. foot.

Partially rotted porch beams are repaired with syntactic foam —a mixture of plastic resin and hollow phenolic spheres. (Photo, Bakelite Co.)

(EPOXY BINDER)

Composition	*Parts by weight*
Epoxy resin ERL-2795	30
Epoxy hardener ERL-2793	9
Phenolic spheres BJO-0930	120

Procedure: Add a weighed amount of epoxy resin to a kneader-type mixer. With agitation, add the proper amount of epoxy hardener. Gradually add the phenolic spheres to the mix and continue mixing until a thick, putty-like mass is obtained. This mass may then be hand troweled into place and cured at room temperature. Temperatures up to 212° F. accelerate cure. A foam density of 8.6 lb./cu. ft. results.

Test results indicate that the

upper limit of phenolic spheres which may be used in syntactic foam is 40% by weight or more than 70% by volume. Combinations of phenolic spheres and polyester or epoxy resin can be used to reduce material costs below the costs of the straight resins.

Field experience has shown that the best method of handling putty-like mixes of syntactic foams is with some form of heated trowel. Hot troweling imparts better flow properties to the mixture and makes it easier to form. Heated trowels have been successfully improvised by attaching a standard trowel or other shaped blade to an ordinary household iron or electric soldering iron.

FOAMED SILICONES

BY D. E. WEYER*

Applications

Three ready-to-use silicone powders are available for making heat-stable, rigid foamed structures. Properly foamed and cured, these three powders, Dow Corning R-7001, R-7002, and R-7003, provide foams with a range of physical properties that make them adaptable to a variety of applications, including jet aircraft and guided missiles, as lightweight, stable thermal insulation, or as structural components.

These three, easy-to-handle foam powders offer a number of advantages. Only heat is required to produce expansion—no addition of catalyst or blowing agent is necessary; and, because none of the ingredients are toxic, the need to wear protective masks or gloves during fabrication is virtually eliminated.

Each of the mixes produces a foam with a uniform pore pattern which is predominately spherical and unicellular. Atmospheric pressure and humidity have little effect on their foaming action, and the mold or cavity requires no preheating. The pressure exerted by the foams is practically negligible and the mold can be of light construction. As shown in Table I, p. 357, the density of the foams is determined by the expansion temperature. In many applications the foams may be cured in service.

* Product Engineering Laboratory, Dow Corning Corp., Midland, Mich.

Equal-weight samples of silicone foam and aluminum sheet supporting equal lead weights are exposed to flame. Silicone foam (left) remains rigid and insulates lead from heat. (Photo, Dow Corning Corp.)

Properties of foams

Foamed structures made from these mixes exhibit good physical and electrical properties, low moisture absorption, and are exceptionally heat-stable thermal insulators. (See Table II, p. 357.) Their heat stability is indicated by the fact that samples have been exposed to a temperature of 700° F. for 72 hr. with only slight dimensional change. Total weight loss after this period was less than 10 percent. Similar samples, heated to red heat by direct flame, did not burn and showed only slight surface change.

Both R-7001 and R-7002 can be foamed-in-place between various types of skins. Although R-7003 cannot be foamed-in-place, it is the most rigid of the three at high temperatures and retains the highest order of compressive strength.

At room temperature, foam made from R-7001 has good compressive strength. When exposed to elevated temperatures, however, the foam becomes soft and rubbery without changing appearance. For applications where higher strength at elevated temperatures is desirable, the foamed-in-place assembly can be strengthened through the use of suitable ribbed structures.

This thermoplastic tendency can be applied to advantage in forming the foam to a desired shape before final postcure. After the initial expansion, sections can be cut from the foam and heated again to temperatures around 200° F. At this temperature, the foam softens and it is possible to wrap or form the sections around air ducts, pipes, gasoline tanks, and the like.

Expanded R-7001 is the most resistant to thermal shock. Sample sandwich structures have been cycled between room temperature and 600° F. without cracking. The properties of R-7001 suggest its use in applications where a heat-stable, low-density foam is required, but where high compressive strength at elevated temperatures is not essential.

Although similar to R-7001 in most respects, expanded R-7002 retains a considerable portion of its original strength at temperatures around 500° F. When used as a structural member at elevated temperatures, this foam should be postcured for 48 hr. at 480° F. to increase its high-temperature strength. In other applications the foam will cure and harden during use.

Although R-7003 cannot be foamed-in-place satisfactorily, it is stronger and retains considerably more strength at high temperatures than either of the other two mixes. It is best suited to the production of formed parts. The foam can be cut or carved to almost any desired shape or can be machined to close tolerances.

Sandwich structures can be made by bonding various types of skins to a preshaped block or sheet with adhesives. Appropriate heat-resistant adhesives which may be used effectively for such a sandwich fabrication procedure include Silastic[1] S-2007 and RTV Silastic. Silicone foaming powders will foam-in-place and pro-

[1] Dow Corning silicone rubber.

vide good adhesion to many materials. In some cases, a preliminary surface treatment is advisable (see "Techniques," below).

Limitations

Chief limitation of expanded silicone resins is friability. In many instances this drawback can be greatly reduced with suitable coatings and by foaming-in-place.

The long postcure required for maximum high-temperature strength is also undesirable in some applications. Experimental work on the foams is being directed toward minimizing both limitations along with producing lower-density foams for economical reasons.

The heat resistance of expanded silicone resins, coupled with their low thermal conductivity, suggest a broad potential in the field of high-temperature thermal insulation. At present, principal interest in the silicone foams centers about their use as a foamed-in-place sandwich core for jet aircraft and guided missiles.

Techniques

Dow Corning silicone foaming powders can be foamed to yield heat-resistant structures varying in density from 10 to 18 lb./cu. foot. Expansion takes place at moderately low temperatures ranging from 300 to 350° F.; therefore, no special heating equipment is required. Expansion can be accomplished in a circulating air oven, with strip heaters, heat lamps, or other similar heating devices. In applications where the silicone foams are used as thermal insulation, they can be cured in service.

Procedure

Surface preparation: The silicone foaming powders will foam-in-place and provide good adhesion to asbestos paper and board, glass, ceramic, and silicone laminates without the need of special surface preparation.

Where adhesion to smooth cavity walls is of prime importance, however, a preliminary surface treatment is advisable. The smooth wall should be sanded lightly to remove gloss, and then coated with Dow Corning 994 Varnish which can be applied with a paint brush or spray gun. Heating for 5 to 10 min. at 320° F. drives off the solvent, and leaves a coating that is slightly tacky until it is cured in contact with the foam.

For casting blocks or sheets, the mold form or container is lined with metal foil or heat-resistant cellophane. After expansion, the foamed blocks or sheets can easily be removed from the form, and the foil or cellophane stripped off.

Blocks or sheets can also be cast directly in mold forms, provided the form surface has been properly treated with an effective release agent for rigid silicone foam structures, e.g., Dow Corning C-4182. Its use on cavity walls results in silicone foams with smooth glossy skins which reduce friability. Easily applied by wiping a thin coating onto clean surfaces, Dow Corning C-4182 gives best results if heated for 5 to 10 min. at 300 to 350° F. to drive off solvent and to effect cure.

Expanding and curing: The required quantity of foamable powder can be poured into any opening at the top of the cavity. If the cavity walls are thin and a close dimensional tolerance is desired, outside supporting molds are suggested. One-quarter inch aluminum plates are satisfactory. These molds do not have to be preheated.

After clamping the assembly, heat may then be applied by means of an air-circulating oven, heat lamp, or strip heater to produce the foam.

Foam density obtainable is determined by the expansion temperature. Table I, above, gives typical densities obtainable at the

TABLE I: Effect of foaming temperature on density of silicone foams

various expansion temperatures. The size and shape of the cavity also slightly affect the density of the foam.

The time required for the powder to melt and expand to maximum height is about 2 hours. To insure against shrinkage, however, the structure should be held at the expansion temperature for at least 4 hours. Foamed pieces made up in forms coated with C-4182 can be removed from the form at this point and cured. Mold forms are thereby made available to accommodate another load of foaming powder.

In most applications where the silicone foam is to be used as a thermal insulator, no postcure is necessary because the foam will cure and become hard during use. To develop good room-temperature and high-temperature compressive strength, a postcure of 24 to 48 hr. at 480° F. is recommended. The curing oven temperature should be raised gradually to 480° F. in increments of 25° F./hr., held at 480° F. for 24 hr., and then cooled to room temperature over a period of approximately 4 hours.

Quantity determination: The weight of silicone foaming powder normally required to fill various-size cavities at different expanding temperatures can be determined by means of a simple ratio as follows:

$$\text{Pounds foaming powder required} = \frac{\text{Cavity volume, cu. in.} \times \text{Foam density at expansion temp.}}{1728}$$

or:

$$\text{Pounds foaming powder required} = \text{Cavity volume, cu. in.} \times \text{Foam density at expansion temp.}$$

For a more uniform cell structure, about 10% excess powder should be added to the cavity to assure an overflow.

FOAMED EPOXIES

Epoxy resins can be converted into foamed or expanded plastics which are suitable for many applications, e.g., encapsulation of electronic components, thermal insulation, and as core materials in sandwich-type structures for rigid flooring, bulkheads, doors, etc.

Two-component liquid systems and single-component epoxy foaming resins are available. In both types, a chemical blowing agent must be included in the formulation, as well as the curative. The blowing agent is responsible for liberation of the gas which produces the expansion of the resin. Wetting agents also are frequently included. When necessary, a volatile liquid may be added in order to absorb some of the exothermic heat.

Two-component liquid systems are available which have relatively short working lives. Heat is essential to induce foaming and may be supplied externally or result from the exothermic heat of the curing reaction. When potting delicate components, or if a very uniform cell structure is desired, high exotherms must be avoided. Additional heat-curing generally is recommended after the foaming operation. An excellent foamed cell structure has been reported for an epoxy-polyamide system, which can be prepared with external heating, using dimethyldinitrosoterephthalamide as the blowing agent.

Single component epoxy foaming resins, in powder form, have extended storage lives.

Prefoamed blocks

More recently, a manufacturer[1] has announced the availability of prefoamed blocks of epoxy resin. The blocks are made by simultaneously foaming and curing an epoxy resin formulation under very carefully controlled conditions.

Since the end product is thermoset, it is unaffected by solvents and has a temperature resistance expected of cured epoxy resin. It is classified as a rigid foam and is readily machinable by ordinary woodworking tools. Because of its fine, uniform structure and complete freedom from grain, it may be carved or machined with great ease, leaving a good surface on which finishing coats may be applied. It has exceptionally good dimensional stability and pieces made from the foam show complete freedom from warping and excessive dimensional changes on exposure to moderately elevated temperatures and high humidity. The core structure is essentially unicellular and therefore the material lends itself well to flotation applications.

Large foam blocks available in sizes up to 1 by 2 by 6 ft. are finding particular utility in tool rooms where they are excellent basic materials for templets, check fixtures, and models. Another suggested application is the making of building panels in which the sheets of foam are covered on one or both sides with decorative skins, using either polyester resins or epoxy resins.

Foaming Agents

BY D. J. MASSEY*

The use of foaming agents to produce cellular plastics and rubber products has expanded greatly in the last few years. The variability and uniqueness of properties that may be obtained have allowed manufacturers to produce products of great utility in diverse forms. The general area of cellular products has two major classifications. One is discrete or unicellular material, and the other is continuous or interconnecting cellular material. The unicellular products are generally made from organic blowing agents which, upon decomposition, produce nitrogen. Continuous cellular foams may be made by the use of carbon dioxide (free or from carbonates) or other gases.

Cellular polymers can be made principally by five methods: 1) incorporating a chemical "blowing agent" into a resin or rubber mix to form a gas by chemical reaction induced by heat; 2) incorporating a specific bifunctional compound (i.e., a diisocyanate) into a polyester which reacts to liberate a gas and also to cross-link the resulting foam into a rigid or flexible structure; 3) whipping air into a colloidal resin or rubber suspension and gelling the porous mass, e.g., foamed latex; 4) injecting a gas into a partially vulcanized rubber or resin mix under high pressure in an autoclave; and 5) incorporating a nonchemical gas-liberating agent into a rubber or resin mix which, when heated, releases a gas (i.e., a gas adsorbed on a finely divided solid).

Although all five methods are of commercial importance, only the first two use chemical foaming or blowing agents.

Blowing agents

Blowing agents are chemical additives for plastics and rubber that decompose on heating, yielding gases which produce lightweight cellular products. Several inorganic compounds (e.g., sodium and ammonium bicarbonate, sodium nitrate, ammonium nitrite) have been used for many years as a cheap source of gas for manufacturing sponge rubber. Unlike with the inorganic compounds, use of an organic blowing agent has the advantage that the temperature at which gases are evolved can be closely controlled, and therefore the process of producing evolved gases can be regulated. Organic blowing agents also produce gas under pressure and can develop great effectiveness with relatively small quantities.

Considerable patent activity has been observed for the last year or two, revealing active interest in the development of new blowing agents. None of the compounds revealed have been commercialized. Table I, p 360, summarizes the more important commercial products.

The blowing agent is generally incorporated into the resin via fine grinding with a plastisol. If the plasticizer concentration in the plastisol is too low for proper dispersion or if dry rubber is used, direct milling may be employed provided the stock can be kept below the decomposition range of the blowing agent. The resin or rubber mix containing the blowing agent is transferred to appropriate molds for heating and/or vulcanizing. A two-stage heating cycle is often used with polyvinyl chloride—the compounded plastisol is heated above the decomposition temperature and then cooled to room temperature. The cooled, partially expanded article is removed from the mold and further heated at a critical temperature to attain the desired expansion without deforming the article.

Although expanded rubbers may be highly filled, use of fillers in plastics compositions sometimes becomes complicated because of their adverse effect upon the chemical that serves to supply the gas which acts as the foaming or blowing agent.

For unicellular rubbers, 5 to 10 parts blowing agent per 100 parts of rubber hydrocarbon are used; for unicellular vinyl, the amount varies between 10 and 20 parts per 100 parts of resin.

Bifunctional compound

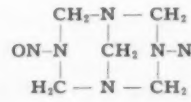
The second major technique, using the reaction of a specific bifunctional compound with a polyester to liberate a gas, is exemplified in the manufacture of urethane or isocyanate foam.

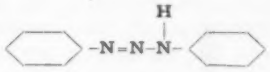
In a broad sense, the use of isocyanates follows the blowing agent concept with the diisocyanate providing the source of the gas (carbon dioxide) as well as the cross-linking medium. The chemistry of the isocyanate foams is concerned principally with the reactions of isocyanates with three types of compounds (alcohols, water, and carboxylic acids) as shown in the following three equations:

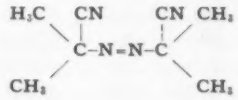
$$RNCO + R'OH \rightarrow RNHCOOR' \quad (1)$$

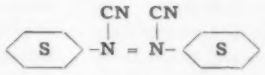
$$2RNCO + H_2O \rightarrow RNHCONHR + CO_2 \quad (2)$$

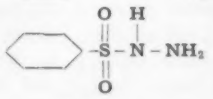
$$RNCO + R'COOH \rightarrow RNHCOR' + CO_2 \quad (3)$$

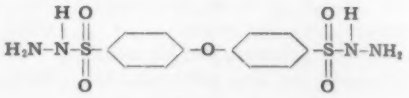


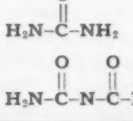












The first reaction is of primary importance in cross-linking reactions, while the second and third reactions serve to generate gas for foaming, as well as cross-linking.

In the preparation of foams, tolylene diisocyanate is used in conjunction with a liquid or low-melting polymer containing reactive groups such as hydroxyl and carboxyl groups. The polymer most frequently used is a polyester. For rigid foams a highly branched polyester is used, while for flexible foams a polyester having only a little branching is preferred.

If the polyester used has a high acid number, reaction of the isocyanate with the carboxyl groups generates the gas for foaming. When polyesters of low acid number are used, 1 to 2% of water is added to decompose the excess isocyanate and thus produce carbon dioxide gas. A tertiary amine

may be used as a catalyst, and an emulsifier may be added as a means of assisting the mixing action.

In the operation, all ingredients may be mixed at one time, using good agitation. Just as the evolution of gas begins, the liquid mixture is poured into the mold or cavity to be filled and the foaming reaction proceeds without the application of heat or pressure. The best physical properties are obtained, however, if a short cure at 70 to 125° C. is used. The foaming recipe must be carefully adjusted to provide gas evolution at a suitable rate and before gelation occurs.

The density of the foam is regulated by controlling the extent of the reaction between isocyanate and water or carboxylic acid. The time and degree of mixing the ingredients must be carefully controlled. The preparation of flexible foam requires 15 to 40 parts of diisocyanate per 100 parts of polyester, while rigid foams usually require 60 to 100 parts of diisocyanate.

How to make Vinyl Foam without special equipment...

Use Du Pont BL-353 Blowing Agent

To stimulate your inventive mind, here are just a few typical examples of the wide variety of products being made from vinyl expanded with Du Pont BL-353.

Du Pont BL-353 is a chemical blowing agent. For ability to produce expanded vinyl with a wide range of physical properties it has no equal. Here are a few of the many advantages you can derive from using this general purpose blowing agent:

No Special Equipment

With Du Pont BL-353, low density vinyl foam can be made at atmospheric pressure without any special equipment.

Can also produce Cellular Vinyl

BL-353 is equally well suited for producing cellular vinyl, in which, unlike vinyl foam, the cells are not interconnected.

Wide Range of Properties

With only slight variations in the formulations and processing conditions, vinyl foam or cellular vinyl can be obtained in a wide range of physical properties—from rigid to soft and resilient, and in densities ranging from 2.5 to 35 lbs. per cu. ft.

Uniform Cell Structure

BL-353 produces vinyl foam and cellular vinyl with fine, uniform cells in either thick or thin sections. With dielectric heat for fusion and curing, vinyl foam slabs up to 6 inches in thickness can easily be produced.

Variety of Colors

Foam in a variety of colors (including snowy white) can be made with BL-353 because it imparts no color or odor to the resin.

CELLULAR VINYL OR VINYL FOAM—Both types of expanded vinyl can be made with Du Pont BL-353. Pictured above, approximately 1/12 actual size, are products made of both types in a wide range of physical properties. The slab cushion, fish net floats and boat fender are of cellular vinyl (all by Linen Thread Co.). The thin sheet and belt (Crest Chemical Industries Corp.) and the two children's toys are made of vinyl foam. The shoe soles (Foam King, Inc.) are made of both cellular vinyl and vinyl foam.

WRITE FOR BULLETINS, SAMPLE

Two bulletins which give complete data on BL-353 from chemical composition to uses and availability, are yours for the asking. Ask for a sample too, for testing in your own production equipment. Chemicals for Plastics

Organic Intermediates

Broadly speaking, the basic raw materials used in the synthesis of commercial plastics are: salt, sulfur, lime, air, water, coal, petroleum, and cellulose.

Salt: Electrolysis of salt in water solution yields chlorine, sodium hydroxide, and hydrogen. Hydrochloric acid is produced by burning chlorine in the presence of hydrogen.

Sulfur: Sulfuric acid is obtained by the catalytic oxidation of sulfur dioxide, produced by burning sulfur in air to sulfur trioxide, which with water yields sulfuric acid. This and other inorganic compounds of sulfur are used to produce a large variety of resins and plasticizers.

Lime: Lime is calcium oxide which is prepared by removing carbon dioxide from limestone (calcium carbonate) by heating (calcining). Its significance to the plastics industry lies in its reaction with coke at a temperature of about 3600° F. to yield calcium carbide, which is used for the manufacture of acetylene.

Air: Oxygen and nitrogen are available in inexhaustible quantities in the atmosphere. The former is used directly in oxidation processes or may be obtained in concentrated form by fractionation of liquefied air. Nitrogen from air is the chief source of ammonia and nitric acid.

Water: Water serves as the primary industrial source of hydrogen used in the manufacture of hydrochloric acid, ammonia, and hydrogenated products. Methyl alcohol is formed by treatment of a mixture of hydrogen and carbon monoxide. Partial oxidation of this alcohol with air yields formaldehyde, an important chemical in resin manufacture. Water is an essential raw material in the synthesis of acetylene from calcium carbide. Water is further reacted with acetylene to form acetaldehyde.

Chemicals from coal

Large quantities of bituminous coal are carbonized in chemical-recovery coke ovens to make coke and "coal chemicals." Economically, the principal product is coke, most of which is consumed in the blast furnaces of the steel industry to convert iron ore into pig iron. As a result of this economic condition, production of coal chemicals is largely geared to demand for steel, and not to demand for the chemicals by the plastics industry and other consumers of these products. Despite this limitation, huge quantities of coal chemicals and their derivatives are used in the manufacture of plastics.

For the plastics industry the coal chemicals that are by far the most important are benzene and naphthalene. Benzene is the prime chemical used for synthesis of phenol, which is chiefly consumed in making phenolic resins. Benzene is also used in equally large quantities for the synthesis of styrene, the monomer for production of polystyrene. Maleic anhydride and other intermediates also are synthesized from benzene. The largest use for the naphthalene from chemical-recovery coke ovens is its controlled oxidation to phthalic anhydride, used in large quantities for the manufacture of alkyd resins and plasticizers. Until recent years benzene came exclusively from the carbonization of coal, but the limitations mentioned above have led to some supplementary production from petroleum during the last few years. Coal carbonization is still the only commercial source of naphthalene.

Among the other chemicals recovered from the tar and the light oil of coke-oven plants are cresol and other tar acids used in making certain types of phenolic resins, and toluene, xylene, coumarone, and indene, all of which find use in manufacture of some plastics and resins.

The hydrogenation of coal is a potential source of the same types of chemicals now recovered from coal-carbonization plants. Although this process has not yet attained full-scale commercial use, it is a promising future sup-

Isobutyronitrile (Eastman Chemical Products, Inc.), derived from isobutyraldehyde, is now available in commercial quantities. This short, compact molecule has a reactive nitrile group available for various additions. Thermal cracking, selective oxidation, or dehydrogenation produce methacrylonitrile.

Alpha-olefins derived from fatty alcohols (Chemical Products Div., Archer - Daniels - Midland Co.) are almost colorless, odorless liquids at room temperature, with unusual reactivity and good solubility characteristics.

Two novel epoxy compounds, dipentene monoxide and alpha-pinene oxide (Becco Chemical Div., Food Machinery and Chemical Corp.), are suggested for use as intermediates in the manufacture of plasticizers, protective coatings, insecticides, bactericides, lubricant additives, adhesives, flotation agents, perfumes, flavorings, and pharmaceuticals; as reactants in organic synthesis; and as solvents.

A hydrocarbon oxidation process (Scientific Design Co., Inc.), by which a variety of aromatics are produced from para-diisopropylbenzene by air oxidation, will be used to manufacture phthalic anhydride, isophthalic acid, terephthalic acid, dimethyl terephthalate, dimethyl isophthalate, and benzoic acid (Standard Oil of Indiana).

Methallyl chloride (Organic Chemicals Div., Food Machinery and Chemical Corp.) can be self-polymerized or copolymerized with a wide variety of reactive monomers.

Triallyl citrate (Chas. Pfizer and Co., Inc.), a new industrial chemical, is particularly useful in the plastics industry as a cross-linking agent for polyester resins. It can be polymerized to hard, brittle thermoset polymers.

A new chemical building block, glycidyl methacrylate (*GMA,* Du Pont Finishes Div.), offers a convenient way of introducing epoxide groups into vinyl polymers or, conversely, vinyl groups into condensation polymers. The monomer will polymerize thermally, with ultra-violet light, or with the usual free radical or ionic polymerization catalysts.

A pure form of *d*-limonene, used in the production of synthetic terpene chemicals and resins, is now offered in tank-car quantities (Florida Molasses Corp.); *d*-limonene is the main constituent of orange and grapefruit oil and is recovered as a by-product in the manufacture of citrus pulp and molasses.

An acetal resin (*Delrin,* Du Pont), made by the polymerization of formaldehyde, has an excellent combination of high tensile strength, toughness, high melting temperature, good fatigue life, dimensional stability, solvent resistance, and resistance to deformation.

A new saturated fatty alcohol (*Adol 45,* Chemical Products Div., Archer-Daniels-Midland Co.) is a long-chain diol with a high melting point of 69° C. It is a practically odorless hydroxy stearyl alcohol derived from hydrogenated castor oil.

Commercial production of pure-grade flake trimethylolpropane (Chemical Div., Celanese Corp. of America) at a lower price makes possible economical use of this high-quality aldol product in a number of basic processing areas. Trimethylolpropane is an important component in production of polyurethane and alkyd resins.

Two chemical products of pine gum, developed by U.S. Department of Agriculture scientists, are now available commercially. The first, maleopimaric acid (Eastman Kodak Co., Distillation Products Div.), has applications in products requiring a plasticizer, emulsifier, or resin. The other, pinane hydroperoxide (American Cyanamid Co.), is a catalyst with applications in the production of certain plastics.

Four silicon chemical intermediates (*Organo-Functional Silanes,* Silicones Div., Union Carbide Corp.) can be reacted with organic chemicals as organic chemicals. They are useful in the modification of ingredients of emulsifiers, antistatic agents, sizing and finishing agents, synthetic resins, and others.

Four reactive, unsaturated monomers (Ohio-Apex Div. of Food Machinery and Chemical Corp.) are capable of being polymerized into hard, infusible resins. Three of the materials (diallyl adipate, diallyl diglycollate, and diallyl isophthalate) are difunctional; the fourth (diallyl maleate) is trifunctional. These monomers are suggested as cross-linking agents for all types of reinforced plastics operations.

Surface-active lignin sulfonate (*Orzans,* Crown Zellerbach Corp.) precipitate readily from solutions and cling to fibers or other materials present. The product is used as a binder for fibers, retention of fines, an emulsifier, an emulsion stabilizer, a flocculant, a dispersant, an extender in polyvinyl adhesive, and as an ingredient and extender in phenolic resins.

Titanium trichloride (Stauffer Chemical Co.), used as a catalyst in the production of polyolefins, is now available in quantities ranging up to hundreds of pounds. The material, which is a dark purple powder with a density of 7 to 30 lb./cu. ft., is soluble in water, ethyl alcohol, and acid solutions and insoluble in ethyl ether and organic solvents.

A new polyester resin incorporating isophthalic (Oronite Chemical Co., subsidiary Standard Oil Co. of Calif.), it is claimed, can be diluted with 10 to 15% more styrene than when using phthalic anhydride and still retain the same level of strength properties.

plementary source of coal chemicals for use in segments of the plastics industry.

Coke finds some important uses in making chemicals for plastics manufacture. When coke and lime (secured from limestone) are heated to a high temperature, calcium carbide results and from this material is obtained acetylene, an important building block for vinyl resins and acrylonitrile. Melamine may also be produced from calcium carbide by a series of chemical operations involving cyanamide.

Coke is also gasified by steam in the water-gas process to make a mixture of hydrogen and carbon monoxide, which may then be catalytically converted into methanol, ammonia, or urea. Controlled oxidation of the methanol yields formaldehyde, an important chemical used in manufacture of resins. Until recent years coke was the sole source of these chemicals but, as is pointed out below, natural gas is now also being used as a raw material.

Petroleum and natural gas

Chemicals derived from these raw materials have recently been called "petrochemicals." The growth of the petrochemical industry has been very rapid and today some of the most useful chemical building blocks for the manufacture of plastics come almost entirely from this source.

The most important of the petrochemicals are the aliphatics, and all but a small percentage of aliphatic chemicals produced in the United States originate in petroleum or natural gas. Ethylene is undoubtedly the most versatile and useful of the aliphatic building blocks used in production of plastics, since it is the monomer of polyethylene. It is used along with benzene to make styrene, and also enters into the synthesis of vinyl chloride and ethylene oxide. Originally, ethylene was recovered from refinery gases as such, but demand has been so very great that now it is largely produced from light hydrocarbons by thermal cracking. Propylene, obtained by similar methods, leads to production of isopropyl alcohol, acetone, and thence methyl methacrylate, also to propylene oxide and other chemicals. *n*-Butylene by dehydrogenation is converted into butadiene.

Natural gas has now largely displaced coke as the raw material for production of the synthesis gas from which ammonia, urea, and methanol are manufactured. As stated before, methanol is the product from which formaldehyde, an important plastics chemical, is produced. In addition to the calcium carbide source mentioned, substantial quantities of acetylene are being made today by controlled cracking.

The aromatic petrochemicals have come along only within the last few years to supplement the supply that for a long period came exclusively from carbonization of coal. Production from petroleum sources is very largely toluene and xylenes, whereas the light oil from coke ovens is predominantly benzene. These aromatic hydrocarbons are obtained by the catalytic reforming of certain petroleum distillates. The petroleum aromatics find much the same uses in the plastics industry as those from coal. One distinctive adaptation, however, is the manufacture of phthalic anhydride by the controlled oxidation of orthoxylene in place of naphthalene.

Probably the most useful agricultural product used by the plastics industry is cellulose, usually obtained from wood or cotton.

When cellulose is reacted with various chemicals, cellulosic plastics are produced. Ethyl alcohol, from which ethylene may be obtained, is produced by fermentation of grain or other plant products. Furfural, from which furan resins are made, is obtained from corncobs, oat hulls, and other farm products. Glycerol, obtained by the hydrolysis of fats and oils, is used in manufacture of alkyd resins. Agricultural products, although having very diverse applications in the plastics industry, constitute a relatively small proportion of the raw materials in comparison with the large contributions from coal, petroleum, and natural gas.

Solvents as intermediates

Many solvents produced from the raw materials described above find use as intermediates for the preparation of other organic chemicals. Solvents can be used directly in resin manufacture, e.g., methanol used for methylated urea textile resins, propanol used for propylated urea coating resins, etc. They can also be used for the preparation of plasticizers, e.g., *n*-butanol used for butyl esters (phthalates), ethylene glycol used for polymeric plasticizers, ethanol used for ethyl esters (phthalates), methanol used for methyl esters (phthalates), etc.

Finally, solvents can be used to prepare resin intermediates. As an example, methanol is used in the preparation of formaldehyde which in turn is used in the manufacture of phenolic, urea, and melamine resins. Another example is ethanol used to make the acetaldehyde and pentaerythritol that goes into the manufacturing process used to make the alkyd resins.

Colorants for Plastics

BY WILLIAM H. PEACOCK*

To produce the many attractive color effects found in modern plastics, the trade colorists and engineers use many synthetic colorants and a few of natural origin. More than 800 coloring agents are domestically available, each of which might be used on occasion with greater or lesser advantage. On the basis of experience, however, colorists have found that only about 10% of these available colorants are needed in order to achieve all of their effects (1,5,6).[1]

There are three special rules plastics technicians should know:

1) Colorants have different properties in different media; therefore, their properties in one plastic are no certain criteria of their characteristics and adaptability to another plastic.

2) The concentration of colorant and used greatly affects the color results, and also may affect many other properties.

Differing techniques used in processing plastics and their different end-use applications usually place major importance on different resistance (fastness) requirements of the colorants.

Good engineering practice requires that each of these factors

RECENT DEVELOPMENTS

An extra-conductive oil furnace carbon black (*Vulcan R XC-72*, Godfrey L. Cabot, Inc.) is available for use in antistatic and highly conductive rubber and plastics compounds. The low resistivity of this new black, compared to other conductive carbon blacks available commercially, is attributed to its small particle size, high degree of permanent chain particle structure, low volatile content, and high surface area.

A new high-strength phthalocyanine blue pigment (*Cyan Blue Toner XR 55-3760*, American Cyanamid Co.) is designed primarily for use by the plastics, rubber, and floor-covering industries. It is said to possess good heat and light resistance and to provide ease of dispersion and good strength development even under adverse milling conditions.

Special dispersions for injection molding (*Formacolor LP*, Westchester Plastics, Inc.) and for extrusion (*Unicolor LP*) of linear polyethylene have been developed. The colorants are mixed in a linear polyethylene base to form masterbatches which can then be extended by the molder or extruder using them.

A colorless fluorescent agent (*Tinopal PCRP*, Geigy Chemical Corp.) converts invisible ultraviolet radiation into visible bluish light which acts to mask yellowing. When used as an additive it improves brightness and whiteness of products made from polyethylene, styrene, vinyl acetate, and other plastics. It comes in powder form and is added to the polymer prior to milling or mixing.

A line of concentrated color dispersions (*"PC,"* California Ink Co., Inc.) offers great color strength and is compatible with a wide range of materials, including cellulose nitrate, acetate, butyrate, vinyl acetate, polyesters, polyurethane foam, chlorinated rubber, and certain acrylics, epoxies, and nylon-epoxy mixtures. The vehicle is a polymeric general-utility plasticizer.

Reduced cadmium pigments (*Cadmopone*, Ferro Corp., Color Div.), available in medium-red, orange-red, and orange, are permanent, nonbleeding, nonfading, and resistant to heat, light, acids, and alkalies. They disperse readily in thermoplastics.

Two concentrated colloidal dispersions of carbon black (*Co-Acrylateblak NC-1401* and *Coblac 405*, Columbian Carbon Co.) offer special advantages and economies to manufacturers of high-grade acrylic lacquers and cellulose nitrate lacquers. Lacquers formulated with these dispersions will produce high jetness, mirrorlike gloss, and smooth surface.

Aqueous colorant dispersions (Kentucky Color & Chemical Co.) are available as high-strength colorants for use in three-component polyurethane foam systems.

Nineteen basic color pastes (*4000 series*, Claremont Pigment Dispersion Corp.) for use with polyester resins produce greater color uniformity in reinforced plastics products than do dry colorants. The pastes are added to the resin before the curing agent.

Twelve color pastes (*Stan-Tone PEC*, Sinclair & Valentine, available from Harwick Standard Chemical Co.) do not retard cure nor accelerate set time of polyesters.

A new color concentrate (*RV-300*, Logo, Inc.) has been developed for silk screening and roller coating of all plastics, except cellulose acetates. Inks are made from the concentrate by adding a clear base and thinners to secure the desired gloss and viscosity.

be taken into account before deciding on the proper colorant to be used.

Rule 1—*Colorants have different properties in different media:* The benzidine yellow toners, for example, have better heat resistance in regular polystyrene than in high-impact polystyrenes. The cadmium reds and yellows, ultramarine blues, and other acid-sensitive colorants are widely useful, yet should be avoided in coloring plastics that liberate acids at high temperatures, e.g., polyvinylidines. In contrast, the iron blues are more suitable for plastics using acidic, not alkaline catalysts.

The nigrosine hydrochlorides, which give excellent gloss blacks in phenolics and cellulose esters, must be used with caution in the aminos, whose curing they accelerate, in shellac compositions, which they quickly "deaden," and in some polyvinyl formulations, in which degradation may be induced. Such stable pigments as the carbon blacks and phthalocyanine blues have strong inhibiting (anti-oxidant) effects on the curing of polyesters and other peroxide-catalyzed polymerizations. Although the titanium dioxides are usually the white pigments of choice for most plastics, they may darken under strongly reducing states. The anatase and rutile types vary in usefulness.

The manganese, copper, and zinc derivatives of colorants may induce devulcanization or degradation, particularly in elastomerics, a feature also shown by some natural earth pigments. While the lead chromate yellows stabilize polyvinyls, the zinc chromates have a reverse effect. Certain vat dyes have good light fastness on cellulosic fillers, yet fade within one or two hours in polyvinyls, and only a few give good results in both applications. A number of "oil-soluble" dyes have very good light fastness in polyacrylates and polystyrenes, yet they tend to fade rapidly in cellulose esters. These same dyes are useful colorants for rigid thermoplastics but effloresce and otherwise migrate badly from plasticized formulations.

Lithol reds often yield brighter color effects in compositions stabilized with barium-cadmium soaps than with certain lead and tin stabilizers. Both dyes and pigments vary in their bleeding resistances in aqueous urea and phenolic-aldehyde glues, glacial acetic acid, rubber cements, and lacquer-type and pressure-sensitive adhesives. Many dyes that are useful in thermoplastics are unsuitable in polyethylenes.

Rule 2—*The effect of colorants tends to vary with the concentration used, not only in color results but in other properties:* Colorants appear faster to light in strong color effects than in pastels and tints, or as a minor component of a colorant mixture. Pigment scarlet is somewhat of an exception for, although it darkens more than duller scarlets, it yields faster pinks or red violets than other organic red pigments. Many colorants crock (rub off) less when used at concentrations below rather than above 0.25 percent. Although small percentages of dyes and pigments have a limited anti-oxidant effect, in larger proportions they may delay for days the oxidative drying of oleoresins and retard or inhibit the complete curing of peroxide catalyzed polymers.

Colorant concentration is also important. Increasing the colorant concentration, for example, can quench the fluorescence, affect bronze (2), and produce the widely prevalent dichromatic effects. Illustrative of dichromatism is the action of F. D. & C. Red No. 2 (C. I. 184), (3) which in gelatin plastics yields magenta (0.05%), scarlet (0.125%), or red orange (0.3%) color effects.

Similarly, most bluish-red pigments yield red violet tints or halftones, and the orange toners commonly yield pink tints. The more transparent pigments may appear black in masstone, an effect which can be overcome by adding some white pigments. For example, iron blues reduce from

(Continued on p. 372.)

COLORANT GROUP CHARACTERISTICS

DYES

By the most generally accepted definition dyes are distinguished from pigments by their property of being soluble in some commonly available liquid, which in the plastics field may vary in nature from alcohols, esters, hydrocarbons, and polyethylene glycols to water. As a group, dyes are also characterized by wideness of color range, brightness, high tinctorial power, good transparency, low specific gravity, and high bulk in air. The individual dyes vary greatly in all the properties that determine their suitability and adaptability for coloring plastics. All will bleed when brought into contact with their solvents.

For discussion of their properties of major importance in the coloring of plastics, dyes may be classified into the following groups:

(1.) *Nigrosines and indulines:* These azine group dyes, particularly the bases, hydrochlorides and sulfonates of the nigrosines, are used in greater quantities than all the other dyes together in the plastics field. They are probably surpassed in volume only by the titanium dioxide pigments and the carbon black rubber-tire fillers. They yield bloomy, gloss black effects, have high tinctorial power, good heat, light (full blacks) and aldehyde resistance. The *bases* are dispersible readily in many types of plastics and, although insoluble in water used alone, they are moderately-to-highly soluble in an amazing variety of other liquids, e.g., in alcohol-toluol (25%), water-acetone (13%) and alcohol-acetone (40%) mixtures, furfural (50%), glycol ethers (10%), polyethylene glycols, fatty acids (30%), fatty acid alcohols, phenol (9%), cyesylic acids (9%), ethyl lactate, dichlorethylene, aniline, nitro and chlorobenzenes, pyridine, dioxan (7%), methyl isobutyl ketone (3%), methyl normal amyl ketone (9%), and diacetone (12%). (Their solutions and/or dispersions in fatty acids are sold as "Oil Blacks.")

Certain grades are useful where dielectric effects are important, particularly in phenolic molding compounds and laminating varnishes. They are resistant to many chemicals, stabilize shellacs, but are less adaptable for polyvinyls, greatly delay the oxidative drying of oleoresins, and tend to inhibit peroxide catalyses.

The *hydrochlorides* yield the same bloomy, gloss blue blacks as their bases and have many of the same resistance and solubility features, although being more soluble (18%) in alcohol. These dye-salts are particularly adaptable for coloring cellulose esters and phenolics, including the cast phenolics, but must be

used with caution in plastics affected by hydrochloric acid because of their tendency to hydrolize at high temperatures.

The *sulphonates* are water soluble (25%), give blue to jet black color effects and have moderate tinctorial power, heat, and light resistance. They are useful for coloring the water-soluble plastics.

(2.) *Oil-soluble and "acetate" dyes:* These dyes are substantially free of salt-forming groups and therefore are insoluble in water, but soluble in a wide range of nonaqueous liquids. They yield a wide range of color effects, are moderately bright, highly transparent, low in specific gravity, have high bulk in air, and good heat resistance. Many tend to soften and melt in the 95 to 140°C. range, making them easily dispersible in hot processing, although some may sublime; yet they yield specky effects, unless carefully diluted, in dry-blend-coloring. They have very good fastness to light in those plastics, such as polystyrenes, which are free of combined oxygen, yet are rather fugitive to light in many other plastics. They tend to effloresce and migrate from plasticized stocks, have moderate-to-very good resistances to aldehydes, and are strong anti-oxidants.

The *"acetate"* types are usually mixed with wetting agents and therefore yield dispersions in water, from which the cellulose esters and some other synthetic fibers selectively absorb them. This dye group, when dissolved in carefully balanced solvent mixtures, is used as 'dip-dye' stains for many thermoplastics.

(3.) *Acid, chrome, direct, developed dyes:* These dyes are usually sodium salts of colorant acids. Of the hundreds available, only a limited number regularly are adapted as colorants for plastics. They yield a wide range of color effects, bright and transparent. In specific gravity they range from 1.05 to 1.5, but because many are usually admixed with inorganic salts, they vary greatly in their bulk in air, dispersion, and solubility properties. These dyes are adaptable to coloring thermosetting, casein, gelatin, and cellulose ester plastics, regenerated cellulose films, and various types of fillers, and are particularly adaptable for compositions having water-soluble phenolic or urea-aldehyde resins, polyvinyl alcohol, methyl cellulose, carboxy cellulose, dextrine, latex, mucilage, starch, shellac, and other water- or spirit-soluble binders. The acid and chrome dyes have affinity for proteins, particularly under acid conditions. The direct and developed dyes are substantive to cellulose fillers, particularly under acid conditions. The direct and denumber of these dyes can be dissolved in glycol ethers to yield stains substantially free of inorganic salts.

(4.) *Basic dyes—basic dye bases:* The colorant nucleus of these dyes is positive, so that they appear as dye chlorides or oxalates (water-soluble) or as bases (organo-soluble), although not all the bases are available. These dyes contain probably the brightest of all dyes, give a wide range of color effects of fine beauty, are transparent, intensely powerful tinctorially, and, in general, have good resistance to heat and aldehydes, but are fugitive to light. They have affinities for amphoteric materials and tannate mordants and are absorbed by some clays. They are highly soluble in alcohols. The bases are also sparingly soluble in toluene. The dye salts tend to hydrolyze and split off acids so that their use should be avoided where this action is important. The *rhodamines, safranines,* and *methyl violets* are available in grades that disperse well in phenolics.

(5.) *Sulfur dyes:* These dyes are soluble in water containing alkaline reducing agents, particularly sodium sulfides or hydrosulfides. They are rarely added directly to resins, but find their greatest usage in coloring cellulosic fillers, particularly for rubber goods. There are no bright red sulfur dyes. In general these dyes show good resistance to light, migration, and reagents, and are moderately heat resistant. As organic sulfides, some stain metal molds and inserts.

(6.) *Vat dyes:* These dyes also are soluble in alkaline reducing solutions, have moderate brightness, low tinctorial power, and very good resistance to heat and reagents, but they vary greatly in light and bleeding characteristics. Helidon pink Pr 109 (1) is used for bright, clean fluorescent pinks in thermoplastics, although having relatively poor fastness to light. Properly applied to cellulosic and amphoteric fillers, many vat dyes have good resistance to fading. When in solid solution in a plastic they tend to be fugitive.

(7.) *Brighteners:* The so-called "brighteners" are a special group of "white" dyes that usually have little or no self-color, but which transmute ultra-violet radiations into intensely bright visible effects. They are useful in plastics chiefly as "bluing agents" and ultra-violet absorbers. Many are water-soluble but a few are soluble in hydrocarbons and certain thermoplastics. In general, their heat resistance is good, but practically all are fugitive to light.

(8.) *Ultra-violet absorbers:* These are a relatively new group of organic compounds or yellowish-to-nearly-colorless dyes, generally derivatives of hydroxybenzophenones, which have the property of strongly absorbing radiations having wave lengths between 320 and 390 mu. (the near-ultra-violet range). They are fairly resistant to ultra-violet radiation themselves, and seem to function by dissipating the absorbed energy, probably as heat. (This is in marked contrast to the action of many other absorbers of ultra-violets.) In any case, when used in plastics they tend to improve the resistance of the various ingredients to photolytic attack in that range, particularly in transparent or translucent materials. Consequently, they tend greatly to delay the photolytic yellowing and other light-induced degradative effects in the plastics and to increase the fastness to light of many colorants. As these compounds function chiefly in the ultra-violet "black-light" range, they are, of course, of little aid to colorants fugitive to visible range (daylight) radiations. Most of them are insoluble in water, are soluble in organic (plasticizer) liquids, usually melt below 200° F., are reasonably resistant to heat, and disperse readily in hot-processed plastics (2b).

(9.) *Anti-oxidants—anti-ozonants:* These are usually organic complexes that to some degree tend to protect plastics from aging effects induced by ozone and oxygen. They often have some self-color. Designed to be reasonably stable to processing conditions and to other reagents, their incorporation in rubbers and other elastomers helps prolong the plastics' life.

ORGANIC PIGMENTS

As a colorant group, the organic pigments are characterized by very limited solubility in most commonly available liquids, a wide color range, good brightness, moderate-to-good tinctorial power, generally low specific gravity, high bulking ratios, high oil and plasticizer absorption, and their much greater resistance to bleeding versus dyes (6). Individual organic pigments, of course, vary widely in their resistance properties and adaptability for coloring plastics. They are most generally useful for plastics for interior applications.

Pigments can be divided as follows:

(1.) *Lithol Reds* are a group of vivid, tinctorially strong pigments widely useful where moderate resist-

ances suffice, as in various thermoplastics and rubber. They exemplify the influence of the metal precipitant on colorant properties, as the color, heat, and bleeding fastness tends to increase from the sodium (yellowish-red), barium (scarlet), calcium (crimson) to the resinated calcium maroons.

(2.) *Certain Naphthosol (B.O.N.) reds, Lithol rubine, and pigment scarlet,* and, to some extent, the *barium toners of Lake Red C* comprise a group having the heat, light, and migration fastness to adapt them for coloring heavily plasticized compositions.

(3.) *Toluidine, para* and *chlorinated para red toners, Brilliant Red Lake R, bronze orange,* and the *nitraniline* and *dinitraniline orange toners* comprise a pigment group yielding very bright, translucent scarlet and orange colors, having good tinctorial strength and moderate-to-good heat- and light-resistance, but which have very poor migration resistance in plasticized stocks. They are useful colorants chiefly for amino and some cellulosic esters.

(4.) The *benzidine oranges, benzidine yellows,* and *Hansa Yellows* yield very clean, bright colors, and have moderate-to-good resistance properties. However, they must be used with judgment. For example, the Hansa Yellows give excellent results in urea-aldehydes, but effloresce from many thermoplastics. The tinctorial strength of the benzidine yellows is worthy of special notice, as they are tinctorially twice as strong as the Hansa Yellows and ten times as strong as the chrome yellows.

(5.) The *phthalocyanine greens* and *blues* are characterized by having resistance properties which meet the requirements for coloring many plastics. However, their anti-oxidant effect inhibits the curing of peroxide catalyzed polymerizations, and they sometimes disperse poorly, particularly in dry-blend-coloring processes. Their dark masstones are approached closely and with practically equal fastness, much less anti-oxidant action, and lower cost by the chrome greens and iron blues. Certain types of phthalocyanine blues lose tinctorial strength on aging in some media, probably due to crystal growth and flocculation.

(6.) The *phoshotungstic acid (P.T.A.), phosphomolybidic acid (P.M.A.),* and *tannic acid toners* of the *rhodamines, basic greens, victoria blue,* and *methyl and crystal violets* give bright, transparent color effects and have generally good resistance to heat and aldehydes. However, unlike their effects in certain surface coatings and inks, they all have poor resistance to light and reagents in plastics. They are used chiefly where their dispersion properties are superior to dyes, but, in general, dyes are as useful and cost less.

(7.) *Acid dye lakes—Bordeaux B, Scarlet 2R, Orange 11, tartrazine, fast light yellow, chinoline yellow* and *Patent Blue* dyes are used as the nuclei for pigments, usually on aluminum hydrate substrates. These complexes yield bright color effects moderately-to-highly transparent, reasonably resistant to heat and aldehydes, and with moderate-to-good dispersion properties in most plastics. Their resistances to light and migration are poor, however. The dyes themselves usually show better fastness to light than the corresponding lakes, so that these pigments are used chiefly where their better dispersion properties are essential

(8.) *Carbon blacks* have excellent fastness properties and large quantities are used for improving the weather- and abrasion-resistance of polyethylenes and rubbers. However, they must be used with caution in certain plastics as they are anti-oxidants and tend to inhibit the functioning of peroxide catalysts, to conduct electricity, and have such high resin and plasticizer absorbencies that they may affect flow and flexibility. They may also bleed on occasion, since some of them contain about 0.5% of benzol extractives. Colorwise, they tend to yield low gloss, matte blacks in many media, and give brownish grays, unless toned with *alkali blue toners* or other pigments. Spectrally they are characterized by having rather flat absorption curves over a wide range of wavelengths.

(9.) *Van Dyke Browns* are carbonaceous pigments from humus and peats which give dull brown color effects of moderate fastness. They are more commonly classified with the natural earth pigments.

(10.) *Browns:* Organic pigments for brown color effects are usually blends of orange (or red and yellow) pigments with blues and/or carbon blacks. Most of them yield dicromatic effects.

SYNTHETIC INORGANIC PIGMENTS

As a group, these pigments yield bright colors at strong concentrations but their tints and pastel colors are often dull. With a few exceptions they are tinctorially very weak, have high specific gravities, low oil and plasticizer absorption, are somewhat coarse and hard in texture, but usually disperse well, yet may appear specky in thin films, and have very good to excellent heat, light, and migration resistance. Their chemical resistance, while usually good, varies greatly with the pH conditions. They have much less anti-oxidant effect and better weather resistance than the organic pigments. The iron blues and ultramarine blues are transparent, as are the yellow iron oxides in some media, but most of the group are opaque.

(a) The *titanium dioxide white pigments* are characterized by their relatively high tinctorial strength, excellent hiding power, high bulking values, extremely high opacity (high refractive index), excellent resistance to heat, light, and migration, and very limited chemical reactivity. These outstanding features make them the most efficient white colorants for nearly every plastic, and consequently they are used in larger volume than any other pigment in this field, except for the carbon black rubber-tire stock fillers. There are two series of these pigments, the "rutile" and the "anatase," which, though chemically similar, seem to vary in their structural geometry. The rutile types yield slightly yellower whites (by reflection), are approximately 20% stronger tinctorially, a little more opaque, and somewhat more inert chemically than the anatase types. Both types are very useful for producing translucent and opaque effects, the amounts needed varying of course with the thickness of the sheet or piece. For example, the use of 0.05% of a rutile-grade titanium dioxide will impart a fog or haze to the 0.025-in. thick, and an opalescent (not irridescent) effect to the 0.200-in. step of the familiar stepped testing piece, using crystal polystyrene, whereas the addition of 1% of the pigment will produce opacity in the 0.025-in. step.

These pigments scatter light so greatly that the addition of 0.1% usually is sufficient to "bring out the color," that is, to convert blackish and dark masstones into undertone effects. Similarly, by adding 2 to 10% of these pigments to dark phenolic and petroleum resins, shellacs, asphalts, and gilsonites the self-colors of these resins can be tinted from browns to light tans, which can then be given at least soft-toned hues by the further addition of chromatic colorants.

These pigments are often used in the surface sheets of laminates to fill the valleys between the filler flocks, resulting in the production of uniformly-colored rather than mottled-effect surfaces. The un-

treated pigments are strongly hydrophilic, so they can be incorporated in latices and other water-soluble plastics. For dry dispersions, it is advisable to use the special grades produced for those processes. Despite their generally excellent fastness properties, these pigments have the adverse features of being subject to attack by strong reducing agents, may even go slightly grayish in certain aminos, and specific grades, particularly some anatase types, may advance the degradation of polyethylenes and some polyvinyl formulations.

The *zinc sulfides* are white pigments yielding bright whites, have medium tinctorial strength, good hiding power, excellent resistance to light and migration, good heat resistance, and disperse well. They are used chiefly in certain phenolic and urea-aldehyde plastics but should be avoided for polyvinyls.

The *lithopones* are zinc sulfide-barium sulfate complexes that have practically the same properties and uses in plastics as the straight zinc sulfides.

The *zinc oxides* give bright whites, have moderate tinctorial strength, good opacity and hiding power, high specific gravity, good resistance to heat, light, and migration, but are rather reactive chemically, tending to form soaps with organic acids, and may cause hydrolysis of plasticizers at high temperatures.

The *white-lead pigments* give bright whites, have moderate tinctorial strength, good opacity and hiding power, very high specific gravity, and good resistance to heat, migration, and light (darken with sulfur fumes on weathering). These pigments are toxic and somewhat reactive chemically, but they tend to stabilize polyvinyl compositions, although not quite as well as specialty derivatives (i.e., phospites and phthalates).

Antimony oxides yield moderately bright whites, have only fair-to-moderate tinctorial strength, good opacity and hiding power, and good fastness to heat, light, and migration. Chemically they are moderately reactive. They probably find their greatest usefulness in "flameproof" compositions, reducing flammability.

(b) The *cadmium pigments* yield clean yellows, bright scarlets and maroons, dull pastels and tints, but are very weak tinctorially. Their heat, light, and migration resistances are good-to-excellent, and their chemical resistance is good, except to some acids.

(c) *Vermillion* is more useful in artists' paints than in plastics, as its light- and heat-resistance is erratic. *Red lead*, *litharge*, and *orange mineral* are probably used more as stabilizers and primers than as colorants.

(d) *Molybdate oranges* and *chrome oranges* yield moderately bright orange and scarlet blends, have good resistance to heat (although they tend to darken more in intensive mixers than during hot rolling), have excellent nonmigrating properties, darken with light, are resistant to alkalies, but are affected by some acids and reducing agents.

(e) The *chrome yellows* give clean hues initially, but tend to darken and go greenish in color on exposure to light and weathering. It is probable that some small percentage of chromium oxide may form but in any case this darkening in no way detracts from their great usefulness in pigment blends to produce greens. These yellows have a stabilizing action in polyvinyls and are useful in polyethylenes.

Zinc yellow has a bright, clean, greenish yellow hue, but because it tends to leach into water it is used more in primers than in molded plastics and its use in polyvinyls should be avoided.

(f) The *chrome greens* (iron blue-chrome yellow compositions) have dark masstones, clean undertones and tints, very good resistance to heat, light, and migration, little to no anti-oxidant effect, good acid resistance, and are low in price. They have poor alkali resistance. They are useful in peroxide catalyzed plastics. Normally they disperse well, but because of differences in specific gravity, surface area, and particle wetting characteristics, their yellow and blue components may tend to separate in certain applications.

The *chromium oxide greens* are characterized by softness of color tone, weak tinctorial power, opacity, and great durability (being affected only by strong reagents). In combination with cadmium maroons they yield attractive, useful, very fast, but somewhat expensive gray effects.

(g) Although the *ferric ferrocyanides (iron blues)* are usually classified as inorganics, they approach the organic pigments in specific gravity, oil absorption, and transparency, features that make them useful in color filters, in which they tend to absorb the longer wavelengths (red) of light. They have excellent light-, migration-, and acid-resistance, are but moderately heat stable, are sensitive to alkalies, and need the help of sequesterant chelates in certain plastics.

The *ultramarine blues* have outstanding brightness and beauty of hue, good transparency, heat-, light-, migration-, and alkali-resistance. Although sensitive to acids they are widely used for coloring polyvinyls, polystyrenes, urea- and melamine-aldehyde, and polyester plastics. They are less suitable for use in polyvinylidines. Some of these blues, particularly when blended with white pigments, are sold as *"cobalt blues."* These should be distinguished carefully from the *blue-colored derivatives* of cobalt commonly used in coloring ceramics, but some can be adapted for coloring plastics. These latter derivatives give reasonably durable color effects, but are sometimes rather difficult to disperse and have low tinctorial strength.

(h) *Mineral violet* is a manganese complex, has a moderately clean color, low tinctorial strength, high specific gravity, slightly hard texture, and good light-, good migration-, and moderate heat-resistance, is sensitive to alkalies, and degrades elastomeric plastics.

The *ultramarine violets* yield soft-toned, grayish, red violet color effects of very low tinctorial power, which approach the ultramarine blues in properties although not as transparent nor as light resistant.

(i) The *synthetic iron oxides* and *iron silicate blacks* (mineral blacks) give soft-toned colors of low tinctorial power, have high specific gravities, low oil and plasticizer absorptions, somewhat coarse texture, moderate dispersion, and good resistance to heat, light, migration, and chemicals.

(j) *Aluminum* flake products are useful for special "metallic" color effects, particularly in combinations with transparent pigments (iron blues—'blued effects'). Used alone they give opaque, silvery grays with a slight metallic glint, having good tinctorial and hiding power, excellent resistance to heat, light, and migration, and limited resistance to reagents. There are other *metallic powders* available (lead, zinc, zinc dust) but they are rarely used for coloring plastics. Where practical, the premixed pastes (with plasticizers) should be used to avoid dust explosion hazards.

(k) *Luminous pigments:* The luminous pigments are largely specialty metallic sulfide complexes which are characterized chiefly by their property of transmuting ultra-violet radiations into visible light energy. Their color appearance in daylight is generally rather different in hue, very much duller, and much weaker in tinctorial power than their beautiful appearance under ultra-violet ("black") light. The intensity of their brightness in an ultra-violet field may arise from the fact that the light is generated on and emitted by the pigment particles, as in the case of the "brightener"

COLORANT GROUP CHARACTERISTICS (Continued)

dyes. There are two series of these pigments, one which fluoresces, and one which both fluoresces and phosphoresces (after-glows). The luminous pigments usually are high in specific gravity (3.45 to 5.6), have weights per solid gallon of 25.8 to 46.7 lb. (1 lb. bulks 0.0387 to 0.0214 gal.), have good resistance to migration, moderate heat resistance, vary in light fastness, and are moderately resistant to chemical attack, except perhaps to acids. The intensity of their fluorescence can be adversely affected if their somewhat brittle crystal structure is ruptured, so they must receive little grinding, and are therefore preferably used in sheet stocks rather than in thin films.

NATURAL INORGANIC PIGMENTS

The group of natural inorganic (earth) pigments have a limited chromatic color range, being largely limited to soft-toned yellows and browns, have low-tinctorial power, opacity to low translucency, high specific gravity, low oil and plasticizer absorption, hardness and coarseness of texture, and good-to-excellent durability.

(a) The *ochres, siennas, umbers, synthetic* and *natural iron oxides* are used for brown effects in phenolic-aldehyde molding compositions and some other thermosets and thermoplastics. Often they contain impurities that induce degradative effects; the coarser types have been known to plug gates and small diameter sprues and give specky color effects in thin films. At high temperatures, the hydrates tend to lose water and go redder in hue.

(b) *Mica flakes* impart to water-white crystal stocks peculiar grayish effects approaching but more translucent than aluminum flake 'metallics'; the chief use is as fillers to improve electronic properties.

(c) *Aluminum hydrates, barytes, bentonite, calcium carbonates, china and other clays, diatomaceous earth, emery grits, infusorial earth, magnesium silicates, silicas, stearates (soaps), talcs* and similar extender pigments have very weak tinctorial strengths and vary widely in transparency and resistance to heat and chemical action, but their presence as fillers often affects the final color appearance, the color uniformity, hue, brightness, translucency, specific gravity, flow, curing rate, chemical stability, durability, and sound records reproduction properties ('surface'), abrasiveness and abrasion resistance. Some tend to absorb or form complexes with certain water-soluble dyes. The metallic stearates are used primarily as lubricants, stabilizers and gelling agents (plastigels). The dye stearates are "oil-soluble" dyes.

(d) *Specialties:* Certain pigment manufacturers have developed specialties and standard pigments designed to be particularly adaptable to plastics.

(Continued from p. 368.)

blacks, through royal blues, to baby blue tints. Some pigments, such as the cadmium reds, give clean, bright reds, but dull pinks.

Rule 3—*Different processing methods and various applications of plastics usually stress different colorant properties:* Probably no available colorant will meet every coloring requirement. Consequently those who write the specifications should defer to practical considerations and knowledge. For example, it is impractical, and usually as uneconomical, to require a colorant resistance of 500° F. for use in a plastic never processed above 350° F. as it would be to require baby panties to be fast to weathering. Again, the chemical resistance varies in severity and nature for colorants added before rather than after a polymerization or condensation step; for reworked stock rather than for virgin stocks; for containers for pharmaceuticals rather than in cake-boxes; for pipe lines rather than pipe-stems; and for filter-press gaskets rather than for fruit jar rings.

Alkali resistance is highly important for colorants for floor tiles and washing machine impellers, whereas acid resistance may be needed for battery cases. Colorants for dentures and baby toys must not bleed into saliva, while fastness to perspiration is more important for tool handles. Different types of migration fastness are needed for upholstery pipings, to avoid wet transference to paper interleavings, in washing versus dry-cleaning operations, in greaseproof wrappers, and for noncrocking sheet stocks. Dyes for shoe-heel films and fountain pen barrels must meet gloss and solubility specifications of lesser importance for certain electrical goods, while the latter uses may require limiting chlorine-content and dielectric specifications.

The particle size and dispersion properties of pigments are more important for thin-gage inflatables (lumps cause pinholes) and in die extrusions than in thick sheets and knife-coatings. Transparency is essential for jewels and automobile tail-lights, whereas standardized translucency is needed for many lighting fixtures, and certain stocks may have shadowproof opacity requirements. Colorant fastness to light specifications rightly are higher for outdoor than for interior end uses; for light-resistant plastics than for those which quickly go yellow or self-darken photolytically; for window draperies than for dress shields and trusses; and may be of only minor interest in parts hidden from view inside a machine. Unlike the two halves of an electrical plug, a thick-walled box and its thinner-walled cover may be subjected to different molding conditions, yet in both cases color difference tolerances may have to be much smaller than for many single pieces.

Recoloring scrap stocks

The recoloring of scrap and reworked stocks is a specialized art, particularly with mixed multicolored materials. It is important to note that the stability and fastness properties of the colorants originally present or developed by aging (yellowing) and processing (toasting) are reflected in the properties of the final color match. Scraps containing fugitive colorants will tend to give fugitive final color effects. The relative transparency or opacity is also a factor. Moreover, dark-colored stocks usually must be lightened in "color value" and "saturation" before they can be recolored to brighter hued effects (usually accomplished by adding white or light gray pigments). Often however, the amounts of such pigments that may be added might be limited by their tendency to

absorb plasticizers (oil-absorption) and thereby reduce greatly the flow characteristics of the stock. Accordingly, when this occurs, the addition of some virgin stock may be necessary in order to permit more pigment to be used.

LUMINOUS PIGMENTS FOR PLASTICS*

Luminescence is the phenomenon which results from the absorption of light energy of one band of wave lengths, and the emission of this energy (with some loss) at longer wave lengths. If luminescence persists for a noticeable duration after the exciting radiation is removed, it is called phosphorescence.

Phosphorescent molding compounds: These compounds emit a glow in darkness that lasts for as long as 10 hr. or more, depending upon the intensity of activation and type of base used. Plastics available in phosphorescent form include styrene, butyrate, polyethylene, acetate, vinyl, acrylic, and polyesters. Originally, these were used primarily in the manufacture of toys and novelties, but are now finding application in such fields as electronics.

Phosphorescent plastics, when exposed to light, have a high initial brightness in the dark, depending upon the activation given. The distance at which objects will be visible depends on the surface area and the amount of pigmentation used. The daylight color in most cases is ivory and the afterglow is blue or green. The green, while having a high initial brightness, has only half the life of the blue afterglow.

Fluorescent pigments are characterized by the emission of radiation from a substance while it is excited by incident radiation. They have no perceptible afterglow and require a light source which produces little or no light. This source is called black light and radiates ultra-violet light energy within the spectral range of 3200 to 4200 angstrom units with the peak of energy radiation at 3600 to 3650 angstroms.

There are two distinct types of fluorescent pigments or dyes: organic dye intermediates and synthetic dyes which are not adaptable to plastics and inorganic pigments.

Inorganic pigments (e.g., Derbylite[1]) are specially manufactured sulfides or combinations. They differ chemically from organic or radium-activated luminous pigments and derive their fluorescent characteristics from a high-temperature heat-treating process. In general, the inorganic fluorescent pigments of the sulfide types have greater light fastness and are adaptable to all types of thermoplastics and thermosets. These pigments are stable and will withstand outdoor exposure over an extended period of time, provided they are used in connection with the proper vehicle. They can be made to withstand heat up to as high as 1800°F. and have been used successfully in polyester bases for silk screening inks.

Destaticizers

BY E. E. ZIEGLER*

RECENT DEVELOPMENTS

A slip agent (*FO-255 Slip-Eze*, Fine Organics, Inc.) for use in polyethylene has antistatic properties, does not impart color to the product, is low in soap and fatty acid contents, and low in toxicity. The material is supplied as a dry powder to facilitate mixing with the extrusion compound.

An all-purpose plastics cleaner (*Spac*, Edison Chemical Co.) claimed to have prolonged antistatic effectiveness is applicable to all plastics materials, fibers, and coatings. The company states that it will not cause crazing or discoloration, or in any way affect the surface finish.

A compounding material (*Antistat A*, Baird Chemical Corp.) for plasticized vinyls renders the product virtually free of static charges. The destaticizer is a compatible, conductive liquid, light amber in color, which is easily incorporated into the resin without noticeable effects on the properties of the vinyl.

An antistatic coating (*Gencote 108*, General Plastics Corp.) for industrial equipment is based on polytetrafluoroethylene (*Teflon*) modified to be electrically conductive. It achieves an antistick, dry-lubricated, chemically inert surface.

Static dust collection in processing, display, and use of molded plastic parts is of widespread concern. Nearly all thermoplastic and thermosetting materials are affected to some degree, the former more severely than the latter.

As a result of investigations into the origin, polarity, and magnitude of static charges on plastics, much has been learned which, although it has not yet resulted in widespread use of destaticized plastic materials, has led to the development and use of a number of destaticizers for application to the surfaces of finished molded articles.

Static on polystyrene

Polystyrene is more apt to accumulate dust deposits than any other thermoplastic. The excellent electrical characteristics of polystyrene have been recognized for years and used advantageously in a wide variety of applications. Unfortunately, the high resistivity of polystyrene does not permit static electric charges that develop on its surface to be neutralized or to be conducted to ground. For this reason, it holds static charges for long periods of time; the result is a tendency to attract and accumulate dust particles. This problem is most severe when colorful polystyrene moldings are exposed in a dry, dust-laden atmosphere. The dust accumulations that result are anything but attractive. An attempt to dust off or remove the dust particles by wiping usually results in aggravating the problem.

Creation of potentials

It has been shown that both positive and negative charges exist at random on any untouched surface of molded polystyrene. The highest charges, ranging in potential up to 10,000 v. or more, are of positive polarity and are created during the separation of the chilled molding from the metal mold. The charges of lower potential may be either positive or negative, and may be the result of molding or hot-processing, fabricating, wrapping, polishing, or simply normal handling and storing.

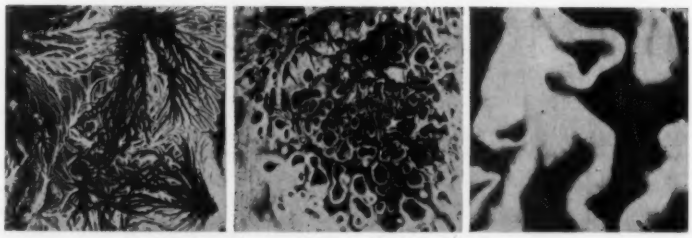
Airborne dust is attracted to and held by the highest electrical charges in the form of branched patterns which, because of their heavy deposit and their resemblance to lightning discharges, are often highly visible and hence very objectionable. Once this type of dust pattern is removed or even disturbed, it will never reappear, except under highly artificial conditions. Dust deposits on static charges of lower order more often take the form of small spots, streaks, or broader smears, sometimes singly, sometimes in combination. Even though removed, they can easily be recreated by a variety of treatments.

There appears to be no relation between dust pick-up by polystyrene and the size, shape, or flow pattern of any molding. Mold lubricants, dyes, and even metallic pigments have no beneficial effect. On the other hand, some mold lubricants appear to aggravate formation of the objectionable branched patterns on polystyrene, and it is known that injection and compression molding processes are worse in this regard than extrusion.

High humidity has no beneficial effect on polystyrene. However, it has an effect on the dust itself and results in decreased dust collection during the more humid summer months.

Preventives

Limited amounts of radioactive elements are ineffective in reducing static effects in polystyrene. Larger amounts are both expensive and hazardous from the health standpoint. Regardless of the amount, at least some forms would be short-lived. It appears that radioactive ingredients do not provide a practical answer to the dust collection problem.



X-ray treatments are effective for a very limited time. Ultra-

* Plastics Technical Service, The Dow Chemical Co., Midland, Mich.
Recent Developments and References were prepared by the editors.

violet radiation is effective only after surface degradation becomes visible. Sulfonation of molded parts is effective, but is hazardous and at the same time rather short-lived.

Of all the plastics tested, polystyrene appears to be the worst from the standpoint of static dust pick-up. Polymethyl methacrylate and polyethylene are next in line, followed by the remaining thermoplastics and thermosets. This correlates with calculations and measurements of surface resistivity, the property that controls the rate at which a static charge can leak off.

If the basic nature of polystyrene could be changed to the extent of making it a conductor instead of an excellent electrical insulator, or if a permanent conductive layer could be established around the material, the problem of static dust attraction would be eliminated. Incorporation of hygroscopic materials in or on the surface of polystyrene might provide a possible solution to the problem, but only if other characteristics such as moldability, heat distortion, and mechanical strength do not suffer because of such incorporation.

Static dust patterns on polystyrene (based on Woodland-Ziegler technique): left—branched pattern; center—spots; and right—smears. (Photo, Dow)

At the present time, the most practical answer appears to be the application of as effective, as permanent, and as inexpensive a destaticizer as can be found (Table I, below).

Mold Release Agents

SILICONE MOLD RELEASE AGENTS

BY T. A. KAUPPI*

Silicone release agents separate most plastics cleanly from fabricating equipment, impart a fine finish to the completed part, and help reduce scrap. Because they are exceptionally heat-stable and will not decompose readily, silicone release agents cause little, if any, staining or discoloration of the finished product. They leave no carbonaceous residue, create no dust problem, and markedly reduce clean-up time and mold maintenance.

As a result, silicone release agents are widely and successfully used in a variety of fabrication techniques, including compression, transfer, and injection molding, and in extruding, sheeting, embossing, rolling, and forming plastics.

Types of materials: Many factors are involved in the selection of a release agent. The plastic used, the molding method, the nature of the finished product, and many other similar considerations play a part in determining the suitability of release agents.

To meet different combinations of these factors, silicone release agents have been developed in several forms: solvent-free fluids, emulsions, grease-like compounds, solvent dispersions, and heat-cured resin coatings. Individual situations are often very complex, and actual testing under production conditions is the best method of determining what silicone to use and how best to use it.

Mold preparation: Mold surfaces should be clean and free of organic coatings or films before the silicone release agent is applied.

New or freshly cleaned mold surfaces may need to be conditioned or "broken in" before the release agent is used. This may be done by applying a solvent dispersion of a silicone release agent such as Dow Corning 7 to the surface, then heating to molding temperature or higher for a period of time. Metal molds, for example, are often heated for 1 hr. at 500° F. After the mold is cooled and excess compound wiped off, release coating is applied.

Application of release agent: Methods of applying the silicone release agent vary, depending on the type of fabricating and the results desired. Similarly, the concentration used also varies.

In some applications, various forms of silicone release agents can be used interchangeably; in others, only one form will work effectively. In some applications, the release agent is applied every cycle; in others, the release agent is used in a manner that gives optimum, multiple release from a single application. Literature is available from manufacturers that lists typical field uses.

The silicone release film may, in some cases, interfere with the painting of plastics. If paint or some other finish coating is to be applied to the molded part, the use of a silicone release agent should first be thoroughly tested. Some silicone films may be removed by wiping with solvent, washing with detergent, or immersing the part in alcoholic-sodium hydroxide solution.

NON-SILICONE MOLD RELEASE AGENTS

BY ERIC O. SONNEMAN†

Mold lubricants, used to solve problems of mold release, fall roughly into three categories: 1) powder or powder-like materials; 2) oils and waxes; and 3) water-soluble waxes, the newest form.

Powders: Aside from graphite, stearates have been the most effective and widely used, including aluminum, barium, butyl, calcium, lead, magnesium, and zinc stearate. The latter has been used in preference to all other stearates. Rejects caused by dust particles have contributed to the diminishing use of these lubricants.

Oils and waxes: Materials of this type used to lubricate molds have as their basis mineral oil, tallow, petroleum waxes (microcrystalline), and, particularly, carnauba wax. Carnauba wax is preferred because of its high melting point and pleasant odor. The problem, however, has been how to remove the wax- or oil-containing film from molded parts to ready them for finishing.

Water-soluble waxes: Mold lubricants containing water-soluble waxes have found a ready market because of their extremely low cost, cleanliness, and proper lubrication.

Used widely and for many years in the rubber, metal, ceramic, and textile industries, many of these water-soluble release agents have polymers of lower glycols as their base. Such materials will burn up and leave no carbonaceous residue. Many of these agents also now contain inhibitors to prevent any possibility of rust-formation on molds, and wetting agents to allow their use in "hard" water localities.

Usually supplied in high concentrations, these lubricants may be diluted by the addition of water at a ratio that may be as low as 6 parts water to 1 part concentrate[1] for polyethylene to as high as 8 or even 10 parts water for acetate, methacrylate, styrene, butyrate, etc. The resulting lubricant has been found to give perfect results if sprayed on after every five shots.

Stabilizers

BY GERRY P. MACK*

Basic function of the stabilizers used by the plastics industry is to prevent degradation of plastics materials when they are exposed to heat and light either during processing or during the commercial life of the finished plastic product. The largest market for stabilizers, of course, is in the compounding of polyvinyl chloride resins. Since the processing of these resins is carried out at temperatures of 300 to 400° F. and, in some cases, even higher, it is essential that a good heat stabilizer be incorporated in the formulation.

Degradation by heat

The most important degradation reaction that occurs on heating polyvinyl chloride resin is a rapid loss of hydrogen chloride. This loss proceeds through what is known as a "zipper" reaction (see Fig. 1, below). The hydrogen chloride thus released acts as a catalyst in causing the loss of more hydrogen chloride until the decomposition eventually results in conjugated double bond structures (polyenes).

Heat degradation in the vinyl compounds is accompanied by rapid color changes. From its initial colorless state, the vinyl compound progresses through various shades of yellow and brown, until it finally reaches black—an indication of complete degradation. The mechanism of this dehydrochlorination reaction has been studied extensively (1).[1]

The rate of heat degradation can be further catalyzed by impurities present in the resin itself. Such impurities may be catalyst residue, metal contaminants, etc. The catalyst residue, in particular, can increase the rate of dehydrochlorination considerably.

The molecular structure of the resin itself has an important influence on the stability of the polymer. All chlorines in the polyvinyl chloride molecules are not equally stable and it has been suggested (2) that probably the first hydrogen chloride to be lost at the start of decomposition comes from a position that is inherently less stable than others in the molecules. Virgin and degraded polyvinyl chloride resins have been subjected to ozonization, in order to determine the type and location of these weakened or labile structures (3).

Degradation by light

The effect of heat and light on vinyl polymers is closely related. In the case of light degradation, however, there is a more rapid loss of mechanical properties. Oxidation plays an important part in light degradation and the loss of tensile strength and embrittlement of a vinyl film can be rapid unless it is adequately stabilized.

Light stabilizers are not necessarily related to heat stabilizers. However, the trend towards the use of a mixed system of metallic soaps with chelators and epoxy-type compounds has greatly overcome the early deficiencies of stabilizers. It is now no longer necessary, in most cases, to add separate stabilizers strictly for light stability. (The exception is the ultra-violet light absorbers discussed below.)

The organotin stabilizers have exceptional light stability and are particularly effective for outdoor weathering (especially in clear vinyl compounds). The liquid barium-cadmium stabilizers that contain phosphites, when used with an epoxy plasticizer, have good light stability. Vinyls stabilized with such systems have been known to take from 600 to 1000 hr. exposure in a Fadeometer with no discoloration or loss of physicals.

Action of stabilizers

Despite the extensive work done on the mechanism of degradation, very little has been published on stabilization.

In the case of the metallic stabilizers, there seems to be some evidence that they function by preventing color formation rather than by inhibiting the formation of hydrogen chloride (2, 5). The exact explanation for this action is still vague, but recent experimental work indicates that these stabilizers may act as oxidation catalysts and disrupt the chromophoric polyene groups.

It has also been suggested that metal-type stabilizers may function by reacting with the hydrogen chloride liberated during the processing of the resin to form metal halides.

Not only the type of metal used in the stabilizer but also the manner in which the metal is tied up in the stabilizer molecule can have an important effect on the properties which the stabilizer will impart to the vinyl compound. Thus, the anionic portion of the metallic salt can affect the clarity, compatibility, and other properties of the vinyl compound, as well as the stability. For example, when using metallic salts of alkylated phenols as vinyl stabilizers, it has been suggested that, while the metal radical performs a good share of the stabilizing effect, the alkylated phenol portion functions as an anti-oxidant. The phenol portion may also act as an homogenizer for the balance of the stabilizer system, thereby increasing compatibility and also contributing to better stability.

In order for a good heat and

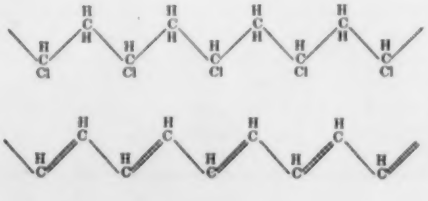

Fig. 1: On heating polyvinyl chloride resin, rapid loss of hydrogen chloride occurs through "zipper" reaction. HCl thus released acts as a catalyst in causing loss of more HCl

Recent Developments and References were prepared by the editors.

A liquid barium-cadmium organic stabilizer (*Flomax 25,* National Lead Co.) is available for vinyl chloride compounds that require both high clarity and excellent heat- and light-stability. It also assures easy incorporation into vinyl systems due to its liquid free-flowing character.

A sulfur-free, all-purpose organotin light and heat stabilizer (*Thermolite 25,* Metal and Thermit Corp.) is said to be effective with all commercially-available polyvinyl chloride and copolymer resins. Vinyl products stabilized with this material possess good optical clarity, do not cross-stain when placed against vinyls stabilized with lead or cadmium, and have good printability and good heat-sealing characteristics.

A heat stabilizer (*Ferro 1827X,* Ferro Chemical Corp.) for use in rigid and plasticized polyvinyl chloride is a mixed cadmium-barium-fatty acid soap with an organic inhibitor. Properties imparted to PVC compounds by the new stabilizer are said to include clarity throughout processing; no exudation on long-term exposure to strong sunlight; and long-term stabilization at moderate concentration levels. Epoxy additives are said to enhance further the stabilization effect.

A one-package liquid stabilizer (Harwick Standard Chemical Co.) for polyvinyl chloride resins and copolymers is compounded of zinc and barium organic salts with a chelating agent. It can be used alone or with some other liquid stabilizers, or some of the epoxy-type plasticizers.

Three new vinyl stabilizers (*Advastabs CZ-11, BZ-51,* and *BC-30,* Advance Solvents and Chemical) are available. CZ-11 is a fluid paste containing government-approved nontoxic compounds of calcium and zinc, and is principally used in calendering, plastisol molding, and extrusion where nontoxicity is the prime requisite. BZ-51 is a liquid barium-zinc compound combining auxiliary stabilizers, and is said to be especially effective with phosphate plasticizers and heavily-filled and pigmented compositions. BC-30 is a liquid barium-cadmium compound combining auxiliary stabilizers and small amounts of zinc, and is a general-purpose material for use in applications where lubrication is not required.

A purified dialkyl phenol sulfide (*Santowhite Crystals,* Monsanto Chemical Co.), a standard anti-oxidant in the rubber trade, is now used as an anti-oxidant in electrical grade polyethylene. It appears to be a good anti-oxidant for polypropylene, which is much more sensitive to oxidation than polyethylene.

3,3'-Thiodipropionic acid (American Cyanamid Co.) and its derivatives are suggested for use in plasticizers and as anti-oxidants in polymers of ethylene. It has a theoretical molecular weight of 178.20, a melting point of 134°C., and is soluble in hot water, alcohol, and acetone. The material undergoes most of the normal reactions of the dibasic acids. The acid, in certain concentrations, is permitted for use as an anti-oxidant in edible fats and oils.

An anti-oxidant (Catalin Corp. of America, under license from Gulf Oil Corp.), for use in plastics, rubber, and other products, is offered in two grades, technical (*AC-1*) and food (*AC-3*). The product, an alkylated cresol, provides protection from embrittlement and discoloration due to oxidation in vinyl, polystyrene, and polyethylene products.

A new zinc organic complex (*Nalzin,* National Lead Co.) designed as an adjunct for barium-cadmium vinyl stabilizers minimizes or eliminates the staining caused by contact with sulfides. This clear, straw-colored liquid has a specific gravity (25°C.) of 0.915 and is miscible in mixtures of hydrocarbons, solvents with ketones, esters, etc.

light stabilizer to function properly, it should have certain of the following characteristics:

1) It should prevent hydrogen chloride split-off or be an acceptor for hydrogen chloride.

2) It should function as an anti-oxidant.

3) It should react with double bonds, i.e., be a reactive dienophilic molecule.

4) It should act as an ultraviolet light screener.

Possessing such characteristics, the "ideal" vinyl stabilizer would be able to prevent color formation in the vinyl compound during processing, would contribute to the production of clear vinyl film sheeting, etc., and would insure production of nontoxic vinyl products with excellent light stability and weathering characteristics. Obviously, however, no one vinyl stabilizer can perform all of these functions and a wide variety of stabilizers are available to handle each of the functions in varying degrees.

It has also become common to accomplish an end-result by combining various materials, e.g., chelators, anti-oxidants, or epoxy-type compounds added to a metallic salt stabilizer. The stability of a vinyl compound is considerably improved with the addition of 5 parts of epoxy plasticizer. The subsequent addition of one part of a barium-cadmium stabilizer improves stability even further and the final addition of an organic phosphite provides still another increase in stabilizing effectiveness.

Chelators

Metallic salt stabilizers are greatly improved as heat stabilizers by the addition of organic phosphites. This type of stabilizer is commonly known as a chelator.

The current theory in regard to these compounds is that they chelate the metallic halides formed during the decomposition of the vinyl compound, i.e., they tie up the byproduct halide into a complex form and thus increase the clarity and stability of the vinyl composition. Ordinarily, as metallic salts function during heat stabilization, they tend to decrease clarity of the compound, presumably because of the metal-

lic halide salts formed. At this point, the metallic halide salts will also serve to increase the rate of decomposition. By adding the organic phosphites to the compound, both of these actions can be arrested.

At the present time, practically all the chelating-type compounds on the market are based on organic phosphorous compounds. Similar derivatives have been used in the lubricating field as anti-oxidants.

Types of stabilizers

Organotin stabilizers: Stabilizers of this type most closely approach the requirements of an ideal stabilizer as listed above. All classes of organotin stabilizers give outstanding clarity whether the vinyl compound is flexible or rigid. They also have excellent light stability, they are known to function as anti-oxidants, and they have been shown to be the only group of stabilizers that can block the formation of carbonyl groups (C = O) (5). There is also a possibility that organotin stabilizers may function as a dienophile.

A mechanism through which organotin stabilizers may function has been suggested (6). The theory is that a butyl group from a dibutyl tin diacetate stabilizer acts as a chain repairer by adding to the polymer. Presumably, the butyl group could add on to the unsaturated portion formed during the extraction of HCl, thus blocking further action as to cross-linking and oxidation at that particular point in the polymer chain. It is further suggested that the tin stabilizer acts as a scavenger for HCl.

Organotin stabilizers are based on a dibutyl tin-R_2 where R is usually an acid, alcoholate, or mercapto group, or some modification of these.

Dibutyl tin mercapto types are the most powerful group of stabilizers known at present. They are being used in very large quantities, particularly for rigid PVC applications.

A speculation as to how these organotin mercapto stabilizers function has been given (7). There is no doubt that the mercapto group can act as an anti-oxidant and further can react with the double bonds formed during the dehydrochlorination and prevent further color development.

The organotin stabilizers have in some cases been recommended for applications in which the toxicity of the stabilizers is a factor.

Recently, di-*n*-octyl tin compounds have been proposed as nontoxic stabilizers for polyvinyl chloride. It is believed that when the alkyl groups bound to tin are higher than four carbon atoms, the toxicity of the compounds is greatly decreased (8).

Barium-cadmium stabilizers: The barium-cadmium stabilizers comprise an important class of vinyl stabilizers. The synergistic action obtained by the use of an alkaline earth soap such as barium with a heavy metal salt such as cadmium has been intensively explored and has led to a whole series of proprietary types of stabilizers based on this action. In the past, barium-cadmium salts of fatty acids (C_8 to C_{12}), generally lauric or mixed C_{12} type acids, have been used extensively. The drawback to using these types of stabilizers is their lack of compatibility and "plate out" during processing. It is well known that these fatty acids have a tendency to yellow when exposed to high temperatures such as are used in processing vinyl compounds. The octoates which are synthetic C_8 acids have been suggested to overcome this yellowing tendency but they have other drawbacks and are rarely used alone.

These stabilizers can also be improved by the use of chelators and epoxy-type plasticizers, but they are still limited by their incompatibility and tendency to plate out.

Because these drawbacks are found in the *solid-type* barium-cadmium stabilizers, there has been a trend to the use of *liquid* barium-cadmium types.

Recent developments in this field indicate that by utilizing an alkylated phenol as part of the anionic portion of these stabilizers, improved performance can be obtained as to heat and light stability, clarity, improved compatibility, and minimum of plate out. These liquid stabilizers contain a higher ratio of barium than cadmium. Usually a chelator is present.

Cadmium stabilizers: Most cadmium stabilizers are used in conjunction with a barium stabilizer, as discussed above. The cadmium stabilizers usually are based on fatty acids such as stearic or the liquid-type octoates. The use of a chelator with such a stabilizer increases its usefulness. Cadmium octoates in combination with chelators and other organic materials have been recommended for some clear PVC applications. They are, however, limited in such applications to those in which the product will not come in contact with water. Cadmium stabilizers, being metallic soaps, when used in vinyl film that is subject to submersion in water, will "water spot" or become completely opaque.

Lead stabilizers: These stabilizers, among the first types known to the industry, are still used in large quantities today, especially for electrical applications. Varieties are many and run from a lead compound litharge to dibasic lead phosphite. The latter most closely approaches the requirements of stabilizers in that it can function as an acid acceptor, act as an anti-oxidant, and can also react with the polyenes formed.

Lead stearate and dibasic lead stearate are good heat stabilizers and have excellent lubricating properties. They are widely used in opaque vinyl compounds, especially for extrusion.

Zinc stabilizers: This type is always used in combination with another metallic salt in PVC compounds. It is most often combined with barium-cadmium stabilizers, particularly the liquid types. In such stabilizing systems, the zinc salt gives better initial color and helps in preventing sulfur stain.

Major limitation of zinc stabilizers is their sudden exhaustion. When improperly used, instead of stabilizing, they can actually cause a rapid degradation of the vinyl compound.

Zinc, in combination with barium or strontium stabilizers, has been recommended for nonstaining applications.

Zinc stabilizers have also been recommended for use with cal-

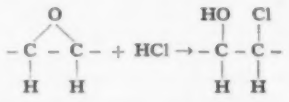
cium stabilizers in nontoxic applications. Several such mixed systems are on the market and have been approved by the U. S. Food and Drug Administration.

Calcium stabilizers: These stabilizers have limited application since they do not impart sufficient heat stability to the material to warrant their use alone in the compound. Calcium stearate is used extensively as a lubricant and contributes slightly to the heat stability of the compound.

At present, so-called "approved nontoxic stabilizers" usually are based on calcium soaps plus other nontoxic metals.

Miscellaneous stabilizers: Barium stabilizers in the form of barium ricinoleate, octoate, or similar soaps, have been used for specialized applications. They do not impart sufficient stability to be used by themselves. Their biggest use is in combination with cadmium or other alkaline earth metals.

Strontium stabilizers have been popular in the past for certain applications, particularly in vinyl coating solutions. They are not used to any great extent at present. Some new stabilizers appearing on the market are based on strontium with barium and zinc, and are recommended for applications where sulfur staining is a problem.



Sodium salts of partial polyphosphoric acid esters have long been used as light stabilizers. They are very poor heat stabilizers and must always be used with an adequate heat stabilizer.

Ultra-violet light absorbers: A group of purely organic compounds that absorb radiation in the ultra-violet portion of the spectrum have become of increasing importance where exceptional light stability is desired. These materials function by absorbing ultra-violet light and dissipating its energy in such a way that it can no longer promote degradation. Materials of this type are based on substituted benzophenones. When used in PVC compounds they contribute to extraordinary light stability. Exposure of compounds so stabilized to 5600 hr. in the Fadeometer has been reported (9).

In general, incorporation of from 0.25 to 1% of these stabilizers is recommended. Their high price, however, has prevented their widespread use in PVC applications.

The ultra-violet light absorbers are recommended for use with polyester resins, methacrylate polymers, styrene polymers, and other similar plastics.

Epoxy stabilizers: The use of an epoxy compound and, in most cases, an epoxy plasticizer, has become a standard part of the formulation of PVC compounds. The ability of the epoxy group to absorb hydrogen chloride is well known and these materials function on this basis, presumably forming the following compound:

The epoxy plasticizers that are the most useful can be divided into three main groups:

1) The epoxy plasticizers based on unsaturated natural oils, particularly soy bean.

2) Monomeric epoxy plasticizers, which are the butyl and higher esters of epoxy stearic acid.

3) Epoxy resins, which are the condensation products of epichlorohydrin and bis-phenol.

The effect of an epoxy plasticizer on the stability of PVC compounds is such that the greatest maximum benefit of these compounds can be obtained by using them in combination with a metallic stabilizer and chelator.

The lower-molecular-weight epoxy resins have limited use in PVC compounds, except in special applications. Their chief drawbacks are high price and relatively limited compatibility with vinyls.

Chlorinated rubber

The requirements for a good stabilizer for chlorinated rubber are, in general, similar to those used for PVC.

The chlorinated film-formers have a tendency to split off HCl even at room temperatures and it has become common to stabilize against this release with epoxy compounds.

Epoxy stabilizers based on the low-molecular-weight epoxy [illegible] ins are most efficient for heat [illegible] bility.

For light stabilizers, the ep[illegible] y compounds are used in comb[illegible] tion with lead stabilizers such as dibasic lead phosphite, as well as barium-cadmium types. As in PVC compounds, no single stabilizer can adequately protect chlorinated rubber and a combination must be used.

Plasticizers

BY GEORGE H. TAFT*

Plasticizers are materials, usually liquid, added to synthetic resins to make the finished product flexible at normal use temperatures or to aid in processing the resins by lowering viscosity of the mixture at elevated temperatures. In most instances, plasticizers are used for both effects.

The first outstanding application of plasticizers in the plastics industry was the use of camphor to facilitate molding and fabricating of nitrocellulose. With the introduction of cellulose acetate and then polyvinyl chloride, the demands on plasticizer manufacturers for products to meet the requirements of these two materials grew stronger. Today, the number of plasticizers being marketed easily tops the 300 figure—with a number of new, improved plasticizer formulations already in the offing.

Mechanism of plasticization

The theories advanced to explain plasticizer action practically always propose formation of some type of loose bond, usually of a polar or hydrogen-bridge type, between the polymer and the plasticizer. This bond formation causes the polymer chains to be pushed apart and to become completely surrounded with a liquid phase. The separation of the polymer molecules is usually observed as swelling. The existence of the liquid cushion around each polymer molecule contributes to softness and flexibility.

Thus, the plasticizing process consists of replacing the polymer-polymer bonds with plasticizer-polymer linkages. This requires plasticizers to have an affinity for the polymer.

Plasticizing action depends upon the types of active centers present in the two materials. For example, esters usually are active toward polyvinyl chloride while water or alcohols are very active plasticizers for the polyvinyl alcohols.

The polymer-polymer bonds present in the original resin cover a broad range of stabilities. Materials which produce plasticizer-polymer bonds of greater stability than the polymer-polymer bonds are active plasticizers and will cause swelling, even at room temperatures.

Primary and secondary plasticizers

Plasticizers are usually classified as either primary or secondary. The primary plasticizer does not bleed or sweat out at normal concentrations and under average use conditions. The secondary type is free from sweating only at low concentrations.

Materials producing bonds of low stability are classed as secondary plasticizers, e.g., alkyl aryl hydrocarbons, etc. Materials forming no bonds are exuded at room temperature, even after processing at high temperatures, and are considered incompatible. In all cases, only a portion of the plasticizer is attached in any way to the polymer, thus leaving considerable free liquid for lubricating effects, migration, and evaporation.

Although plasticization will occur at room temperature with primary plasticizers, the rate is slow. To hasten the process, elevated temperatures and stress, as obtained by milling, calendering, or extruding, are generally used.

Functions of plasticizers

Plasticizers are used to: 1) lower viscosity at the elevated processing temperatures, and 2) impart flexibility to the finished product.

Addition of a plasticizer widens the temperature range over which the polymer normally changes from a solid to a liquid. This is, of course, desirable for processes like extrusion and calendering, but not for injection molding.

The solubility relationship between the plasticizer system and the polymer system is important as regards melting range and viscosity at elevated temperatures. Polyvinyl chloride resins are near ideal because the viscosity-temperature curve at elevated temperatures is relatively flat, making possible practical processing without critical temperature control. With materials such as polystyrene and polyvinyl formal, the viscosity-temperature curve is extremely steep, making processing in a normal manner impossible.

Using the two effects—solubility at elevated temperatures and the effect of the amount of plasticizer on viscosity—the compounder is able to produce a variety of compounds on standardized equipment.

The physical properties of the final compound depend on the amount and kind of plasticizer present. The change of flexibility on lowering temperature is closely related to the viscosity changes of the plasticizer with temperature. As the degree of adsorption on the resin depends on the polar nature of the plasticizers present, the more highly polar, and consequently the ones with the poorest temperature viscosity relationships, are usually adsorbed preferentially. When mixtures of primary and secondary plasticizers are used, this adsorption tends to leave the less polar secondary plasticizers free to act as lubricants and give improved low-temperature properties to the product. By selection of the proper high solvent primary types and use of the proper amount of secondary plasticizer, the compounder can strike a usable average between processing and final properties.

Incorporation of plasticizers

Incorporation of the plasticizer usually begins with a mechanical mixing of the plasticizer with the dry resin, usually by the use of ribbon blenders where the resin is available in powder form. All ingredients of the compound are added to the blender although color pigment may be added later

* Consultant, 9 Monument St., Concord, Mass. Recent Developments and References were prepared by the editors.

Di-2-ethylhexyl isosebacate (*Kesscoflex DOIS*, Kessler Chem. Co., Inc.) when used to plasticize PVC resin contributes good low-temperature properties, excellent resistance to water extraction, and low viscosity in plastisols. It has low volatility and high plasticizing efficiency Di-*n*-butyl isosebacate (*Kesscoflex BIS*) performs similarly to dibutyl sebacate as a plasticizer for PVC, offering high plasticizing efficiency as well as good low-temperature properties.

A primary high-molecular-weight plasticizer (*RC Polymeric BGA*, Rubber Corp. of America) for polyvinyl chloride has good solvating characteristics and superior nonmigrating properties. Compounds prepared with this plasticizer exhibit low volatility, high resistance to extraction by water and oil, and excellent heat and light stability.

A high-molecular-weight polymeric plasticizer (*Emery 3094-S*, Emery Industries, Inc.) features easy processing, light color, and excellent electrical properties, as well as extremely low migration, extraction, and volatility.

A new plasticizer (*Morflex X-1038*, Morton-Withers Chem. Co.) was developed as a replacement for *n*-octyl/decyl phthalates as vinyl plasticizers. An electrical grade plasticizer (*Morflex P-20B(E)*) provides good low-temperature plasticization along with high electrical qualities.

A new modified alkyl phthalate primary plasticizer (*PX-313*, Industrial Chemical Div., Pittsburgh Coke & Chemical Co.) imparts low-temperature flexibility to vinyls equivalent to that obtained with *n*-octyl/decyl phthalates, at an appreciably lower cost. It is recommended for use in high-quality coated fabrics, sheeting, and film; in vinyl jacket wire and other extruded products; and in plastisols.

A phthalate-type plasticizer (*Santicizer 213*, Monsanto Chemical Co.) helps reduce the grip of vinyl chloride surfaces. A 40% content in a formulation gives a Shore hardness of 82 compared with a 73 hardness when a 40% content of DOP is used. It eliminates the need for interleaving in rolls of film, prevents gripping of a vinyl-surfaced product to the walls of cellophane and polyethylene bags, and "slicks" the surface of electric wire coatings.

A low-cost secondary plasticizer (*Chlorowax LV*, Diamond Alkali Co.) for vinyl compounds has low volatility, low migration rate, lack of odor and toxicity, light color, and low viscosity. It is recommended where maximum heat stability and good low-temperature torsional properties are important.

A polymeric plasticizer (*Paraplex G-62*, Rohm & Haas Co.) has been approved by the Food and Drug Administration and the Meat Inspection Branch, United States Dept. of Agriculture, for use in compounds utilized in the packaging and conveying of food products. Approval includes use as a plasticizer in films for packaging bacon, lard, and other meat products in Federally-inspected meat plants, as well as for packaging water-containing food products such as fruits and vegetables.

A new plasticizer (*Plasticizer SC*, Harwick Standard Chemical Co.), a triglycol ester of a vegetable oil fatty acid, imparts low-temperature properties to polyvinyl chloride compositions and nitrile rubber. It is also of considerable value in compounding neoprene. In addition, it is compatible with polyvinyl butyral, polystyrene, coumarone resins, ethyl cellulose, and nitrocellulose. The plasticizer is practically odorless and is soluble in most solvents.

A primary, polymeric plasticizer (*NP-10*, Eastman Chemical Products, Inc.) for polyvinyl chloride compounding is based on neopentyl glycol and combines permanence properties, ease of processing, low-temperature flexibilty, and low color.

A low-cost plasticizer (*Polycon 5B*, Brown-Allen Chemicals, Inc.) for use in vinyl formulations replaces higher-priced *n*-octyl/decyl phthalate where low temperature and low volatility are desirable. In plastisol formulations, it offers good flow-out properties, slow gelation, and fast cure.

N-trichloromethylthio tetrahydrophthalimide, originally developed as an agricultural spray (*SR-406*, Esso Research & Engineering Co.), now shows promise as an additive (*Vancide 89*, R. T. Vanderbilt Co., Inc.) in plasticized vinyl film, making it mold- and fungus-resistant and improving low-temperature flexibility.

---

to avoid contamination of the mixer. With PVC, plasticizers are added by spraying into the mix, preferably hot. The mixing cycle ranges between two and five minutes. The batch may be dumped directly onto a mill, or into a Banbury, or can be barrelled off.

Plasticization is obtained by heating the batch under stress. This may be accomplished by use of rolls operating at differential speeds, a Banbury, or an extruder. Plasticization, complete mixing of the batch, and proper pigment dispersion are obtained in this step.

The plasticized batch is then fed to the final calender or extruder. In some cases, the batch is first pelletized for ease in handling or further compounding.

Plastisols and organosols

The fact that plasticizing action is very slow at low temperature and stress makes possible the

preparation of plasticizer-resin dispersions which can be applied to a supporting medium, usually fabric, or molded before fusion. The dispersion is a viscous liquid which can be applied by the usual coating methods. After application, plasticization is obtained by fusing above 300° F. The heating cycle converts the dispersion to a continuous film or solid.

Such dispersions of plasticizer can be compounded with blowing agents or saturated with a gas, after which the heat cycle causes foaming to produce a sponge product.

Dispersions of plasticizer and resin together with solid compounding ingredients are called plastisols; when more than 10% of a volatile diluent is present, they are called organosols.

As the plastisol viscosity depends largely on the kind and amount of plasticizer present, secondaries such as the adipates may be used solely for their ability to lower viscosity. With organosols, viscosity control is easily achieved by use of the volatile diluent.

Phthalates

Because of the large amounts of plasticizers used with the polyvinyl chloride polymers, most of this discussion will cover plasticizers for PVC, unless otherwise indicated. Plasticizers, of course, also find use in formulations for cellulose acetate, cellulose nitrate, and other plastics as well.

The largest proportion of plasticizers used with PVC is esters, usually of polybasic acids. The phthalates are the major primary plasticizers with the aromatic phosphates leading in the electrical industry. Relatively smaller amounts of the esters of aliphatic dibasic acids are consumed as secondary plasticizers. Due to lack of compatibility, esters of monobasic acids have limited use.

Early studies of the various alkyl phthalate esters showed dibutyl phthalate to be the optimum in solvent power, either increasing or decreasing the alkyl chain length and causing a decrease in solvent power. Because of high volatility, dibutyl phthalate is not used to any extent. The octyl esters are now accepted as the best compromise between solvent power and volatility. The phthalates all show poor low-temperature characteristics. Stability, availability, cost, odor, color, and low toxicity, however, are important in helping the phthalates hold the prime position they now occupy.

The last few years have also seen considerable work being done on developing higher-weight phthalates to replace DOP. The use of mixed alcohols affords some control over temperature-dependent characteristics. Recent products have used alcohols between the hexyl and decyl. The possibility of major improvement in these phthalates is remote, however.

Although the major amount of phthalates are used with PVC, considerable diethyl and dibutyl phthalate go into nitrocellulose lacquers and smokeless powders. Small amounts are incorporated into paint as a plasticizer for alkyd resins.

Phosphates

The phosphates are second in importance in the plasticizer field, primarily because of their low volatility, high plasticizing action, nonflammability, and adaptability to stabilization for electrical use. Their major weaknesses are poor low-temperature properties and odor development. In PVC formulations, the use of small amounts with other plasticizers seems to cause improvement in resistance to bleeding under ultra-violet light. The phosphates generally have a high refractive index, giving additional "brightness" to clear compounds.

An exception to many rules is trioctyl phosphate (TOF). It has a higher degree of compatibility with PVC than expected, although it should be rated as a secondary plasticizer. The low-temperature properties are excellent, but when used alone, processing stability is not too good. When used with primary solvent types, TOF shows a definite tendency to bleed. This spewing does not occur when it is used as the sole plasticizer.

Tricresyl phosphate also finds use as a "chemical type" plasticizer for nitrocellulose coatings.

Plasticizers impart flexibility to the vinyl film and sheeting used in the manufacture of these raincoats and facilitate fabrication. (Photo, Merckon Co.)

Triphenyl phosphates are excellent plasticizers for the cellulose esters while tributoxyethyl phosphate is used for low-temperature purposes with some synthetic rubbers. Considerable amounts of phosphate esters are consumed in such other applications as hydraulic fluids, lubricants, gasoline, and beverages.

Adipates, azelates, and sebacates

Dibasic acid esters are presently limited to the adipates, azelates, and sebacates. Isosebacic acid is becoming available and will undoubtedly assume a fair part of this market if its price is sufficiently low. Due to relatively low compatibility and high volatility, the adipates are used primarily where cost is a factor. The azelates have been reported as having somewhat better resistance to bleeding under sunlight and heat than esters of the other two acids. The sebacates have generally been used where excellent aging with low-temperature resistance can be afforded in the end-product.

Production of dibasic acids is increasing and the next few years, if research continues at this pace, will undoubtedly see the introduction of many new acids. It is doubtful if this type of simple ester will ever assume a major

portion of the plasticizer market, although their use in making high-molecular-weight plasticizers may be important.

Esters of dibasic acids find their major use with PVC as secondary types. An adipate is finding use with the vinyl butyral, while a sebacate has been used with the same resin in some military items. Dioctyl sebacate and azelate are finding considerable use as lubricants for jet engines as are the adipates in extreme temperature range greases. Some small amount of adipates are used as dielectric fluids.

Maleic and fumaric acid esters have found almost no application as plasticizers. The citrates and related acids have shown promise, primarily because of lack of toxicity. These materials have good solvent power, color stability, and low-temperature resistance but tend to be high in volatility. One of the aconitate esters has found major application with the polyvinylidene chloride copolymers.

The monobasic acids have shown only special application to date. The benzoates, particularly benzyl-benzoate, have some use where a solid material is desirable. The aliphatic acid esters are limited largely to tetrahydrofurfuryloleate and methyl pentachlorostearate. Both these materials are secondary types, with stability limiting their use. The chlorostearate is one of the few nonflammable plasticizers that impart low-temperature resistance and can be stabilized electrically.

Epoxies

Epoxidized materials have established application as secondary plasticizers, their stabilizing action being of particular interest. These are usually made from mono-, di-, or tri-esters of the aliphatic monobasic acids.

Non-esters

A small portion of the plasticizer market is filled with non-ester materials. These are usually chlorinated aliphatic materials, petroleum distillates, ketones, ethers, sulfonamides, and nitro-aromatic compounds. They are primarily used to lower cost where some sacrifice can be made in such properties as low-temperature resistance or volatility.

Polymerics

During the last year, several producers have introduced polymeric types. These materials are distinguished by their lack of volatility. The problem in their development is to strike the proper balance between high-molecular-weight, fluidity, and compatibility. Purchasers of the finished article made of plasticized polymers are tending to specify limits that call for use of major amounts of the polymerics. More types of glycols are becoming available, which is encouraging the development of these polymeric types.

Polymeric types have found their major use with PVC. Some small amounts have gone into synthetic rubber.

Basic raw materials

The sources of acids, anhydrides, and alcohols are today well-established. Phthalic anhydride is produced in large volume. The major quantity of phthalate plasticizers is made by companies not producing the anhydride.

The alcohol supply is very free due to the large excess capacity now present in the oxo plants. This excess of capacity has fostered the development of other alcohols beside the octyl. So far, these alcohols from the oxo process have been selected by the ability to manufacture them from available crudes. Competition will undoubtedly force the production of alcohols selected primarily by their properties in the final plasticizer.

The dibasic aliphatic acid situation is changing rapidly. In the last few years a dependable source of azelaic acid has increased the use of azelate esters. Commercial production of isosebacic acid may cause a general price reduction in the dibasic acids. Very probably, other dibasic acids will become available quickly.

Future trends

One large future use of plasticizers may be with resin which cannot be plasticized at the present time. Development of new plasticizers or of new polymers may make this possible.

The plasticizer market will probably grow directly with the polyvinyl chloride market. The tendency will be to make higher-weight plasticizers, which may cause an increase in the ratio of plasticizer to resin. Foam and plastisol applications use increased amounts of plasticizer and will undoubtedly grow rapidly.

Major changes in plasticizer production depend on the industry's ability to introduce materials with increased molecular weight and fluidity. To obtain high weights by use of polymeric structures will probably not be possible, as fluidity depends on the randomness, or lack of regularity, in the structure. This was first indicated in the patents covering sebacic acid polyesters. Consequently, the use of directed esterifications may be of major importance.

A growing application of many plasticizers is as functional fluids for use as lubricants and as pressure and power transmitter liquids. Future requirements for these applications somewhat parallel those for plasticizer use.

Solvents

BY JOHN W. WYART* and N. G. BAKER*

RECENT DEVELOPMENTS

Ethyl amyl ketone (Shell Chemical Corp.), a new high-boiling lacquer solvent, is now available in unlimited tank-car quantities. EAK is a better solvent for nitrocellulose than any other high-boiler commonly used. It is also used in vinyl coatings and as a starting point for chemical syntheses.

Tetrahydrofuran (Du Pont), a furfural derivative produced from one of the chemicals used in making nylon, is an excellent solvent for high-molecular-weight polyvinyl chloride resin and vinylidene chloride copolymers. Its principal use at present is in a topping coat for coated fabrics. A top coating with high-molecular-weight resin dissolved in THF will help eliminate the problems of crocking, blocking, migration, and marring. Another growing use for THF is in vinyl chloride adhesives where high speeds are necessary. Use of THF in cast vinyl film is still in the development stage. If successful, it may make possible the use of high-molecular-weight resins for cast film and may lower cost because of fast production.

A new thickening agent (*Viscotrol A*, Ferro Corp.) imparts thixotropic body to polar, nonpolar aromatic, and aliphatic solvents, as well as to non-solvent-containing liquid resins and plasticizers. Its ability to body organic liquids is not affected by phenols, polar solvents, water, and slightly acidic or basic components. It will maintain uniform viscosity over long periods of aging.

A liquid defoamer (*Surfynol 104A*, Air Reduction Chemical Co.) is recommended by the manufacturer for use in aqueous systems where foaming is a process problem, or undesirable in the end use. This company markets two other defoamers (*Surfynol 102* and *Surfynol 104-E*).

Solvents are selected from the broad category of industrial chemicals because of a specific property—their ability to dissolve other substances. In a sense, they can be considered as processing agents whose function is to facilitate the use of a solid substance for some particular application.

As these solvents are selected from a large field of chemicals, they often serve multiple functions. In addition to their solvent uses, they can be used as intermediates for preparation of other chemicals, or to supply certain physical properties to a mixture of ingredients. Some applications in which solvents are used other than for their dissolving actions are in extraction processes, concentration of pharmaceutical products, ore flotation, dry cleaning, automobile antifreezes, and hydraulic fluids, among others. A major use for solvents, however, continues to be as processing agents in dissolving resinous substances for the coating and adhesive industries. The textile industry also uses large quantities of organic solvents, particularly in the spinning solutions for cellulose acetate fibers.

* Celanese Corp. of America, 180 Madison Ave., New York, N. Y.

Recent Developments and References were prepared by the editors.

Development

The modern solvent industry started with the fermentation process developed during the first World War for production of acetone and butanol. Acetone was urgently needed for the war effort and, consequently, large facilities were erected for its production. Since butanol was a co-product of the process, it quickly became a surplus item.

For every pound of acetone, 2 lb. of by-product butanol were also produced. The growth which the plastics industry has witnessed is related to this butanol surplus.

In an effort to develop an outlet for this surplus, it was reacted with acetic acid to produce butyl acetate which was found to be an excellent solvent for cellulose nitrate.

Cellulose nitrate, when it was dissolved in butyl acetate and modified with resins, produced a quick-drying, attractive, tough, and durable substitute for paint and varnish needed by the automotive industry. This was the start of volume lacquer usage. Automotive production, which had previously been bottlenecked due to the slow drying properties of the paints previously used, was increased considerably. It was not long before other industries followed the lead of the automotive industry. Artificial leather utilized the new lacquer coating. The paper and furniture industries also began to finish their products with it. With this beginning, it was not long before other means than the fermentation of starch and sugars were used to produce butanol and other solvents for the new coatings industry.

Fermentation is still used as a means of manufacturing solvents. Some ethyl alcohol is produced from the fermentation of grain and black strap molasses and some butanol and acetone are also produced by fermentation. By and large, however, the solvent industry has come to depend on petroleum and coal by-products as a source of raw materials rather than such agricultural products as grain, molasses, corn, etc. Solvents that are manufactured by synthetic methods from these hydrocarbon products are more stable in their price structure than solvents manufactured from agricultural products. These latter types of solvents show wide price

TABLE I: Solvent production statistics[1]

fluctuation as their raw materials alternately become scarce or are in oversupply.

Synthetic production

The first step toward synthetic production of solvents came when the hydrogen and carbon dioxide by-products of fermentation were utilized for the preparation of methanol. In addition to its solvent uses, this alcohol is widely used in automobile antifreezes and as an intermediate for the production of formaldehyde.

Formaldehyde reacted with phenol and urea led to a whole series of new plastic materials which could be utilized in solvent solutions as coatings. It can be seen that the tremendous growth of the coating industry in general is closely intertwined with the growth in solvent production. This came about not only because of the processing improvements in coating application due to the availability of new solvents, but also by the utilization of these solvent materials as chemical intermediates for production of new resins and plasticizers. These in turn prompted the development of new solvents for their processing.

Oxygenated solvents

The volatile polar liquids such as the ketones, esters, glycol-ethers, etc., are of considerable importance in the coatings industry. These solvents are needed to disperse and dissolve the more difficult soluble macromolecular substances.

Esters: The original nitrocellulose solvents were butyl, ethyl, and amyl acetate. In 1955, more than 170 million lb. total of these three solvents were produced, primarily for the coatings industry.

Esters, of which the acetates represent the only commercially important members, are produced by reacting commercial alcohols with acetic acid or anhydride. In some cases, esters are produced as by-products in an ester interchange reaction, or by ester hydrolysis in the presence of alcohol. Methyl acetate, for example, is obtained as a by-product from the hydrolysis of polyvinyl acetate to polyvinyl alcohol. Almost all of the lower-priced alcohols are esterified for use as active solvents for resinous materials. Therefore, as more alcohols are made commercially available, the number of esters available will also increase.

Alcohols: Ethyl alcohol is the most important member of this class of chemicals. It is used as a solvent for shellac and various other resins, as a latent solvent for nitrocellulose, and an intermediate for a great many organic compounds. Ethyl alcohol is still produced in quantity by the fermentation of molasses and grain. In the last few years, however, synthetic material has made heavy inroads into the fermentation alcohol market. The quality of the synthetic product is equal to that of the fermentation grade.

Methanol is produced primarily by direct oxidation of hydrocarbon, although some wood distillation is still carried on. This alcohol is an excellent solvent for nitrocellulose, ethyl cellulose, natural and synthetic resins, etc. It is the most active of the aliphatic alcohols in solvent power; however, its industrial application is restricted somewhat by its high toxicity and its volatility. Methanol finds extensive use as an intermediate, principally for the production of formaldehyde. Both normal propyl and isopropyl alcohols are produced by hydrocarbon oxidation, with the latter alcohol assuming the greater importance. Isopropyl alcohol is produced in the greatest quantity of any alcohol except ethanol. It is used widely as a latent solvent in nitrocellulose lacquers. Its properties are similar to those of ethanol.

Butyl alcohol: All four isomers of butyl alcohol are produced commercially, with normal butyl alcohol finding widest application as a solvent. This alcohol is produced synthetically by the aldol condensation of acetaldehyde.

Higher alcohols: Amyl, hexyl, and octyl alcohols, and alcohols of even greater carbon chain length are produced commercially. Alcohols higher than 6 carbons (hexyl alcohol) are not frequently used as solvents due to their low volatility. These alcohols find widespread use as intermediates for plasticizers where low volatility is required.

Ketones: These chemicals have come into widespread use as solvents for resinous materials. Three are of great commercial importance—acetone, methyl ethyl ketone, and methyl isobutyl ketone. Acetone is the most important member of the group. It is produced in great quantities by oxidation of isopropyl alcohol. Acetone is an excellent solvent for nitrocellulose and most other cellulose resins although somewhat volatile for coating needs.

Methyl ethyl ketone is produced from secondary butyl alcohol. As the second member of the aliphatic ketone series it is less volatile than acetone and hence widely used in coating formulations. Methyl isobutyl ketone contributes flow to lacquers and is a good blush retarder.

Function of a solvent

Most of the resins available in industry for coating purposes are hard and brittle substances.

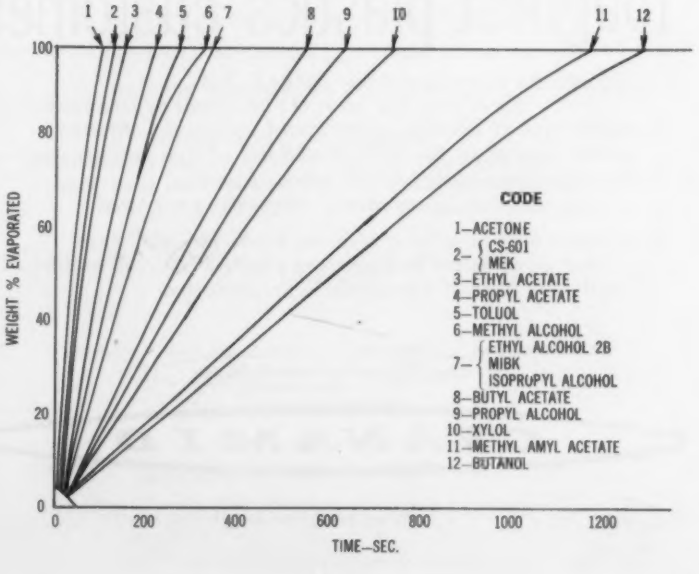
Others are less hard and some are even soft tacky materials. All of these have to be made fluid and the particles welded together to form a continuous film before it can be considered a coating.

Provided the chemical structure of the resin is not altered, this fluid workable state can be achieved by heating the resin or by dispersing it in a solvent. These properties exist only while the heat is applied or while the solvents are in association with the resin. Removal of either causes the resin to revert to its original unworkable state. In this respect, a solvent differs from a plasticizer. An important difference in the use of plasticizers and solvents, of course, is that solvents are always used in fairly large amounts to produce a liquid material, whereas plasticizers are used in smaller quantities to produce a flexible yet still solid product.

In order to understand better the behavior of solvents and resin, we might consider the structure of a resin before and after the addition of a solvent. A resin appears to be a three-dimensional network of macromolecules. Each of these molecules has attracting points along its chain. These attracting points can attract each other, thereby setting up secondary forces of attraction between resin macromolecules. If these attracting centers are many and strong, the forces of attraction will be such that a very close-packed, rigid structure will result. Such a resin will be hard and brittle. If, however, there are few attracting centers, and if they are relatively weak, then a flexible material will result. These bonding forces between molecules are actually equilibrium forces, for if we heat or cool the resin we will affect the properties, thereby indicating that motion resulting from freedom in the mass is still possible. It can be said that an aggregation-disaggregation equilibrium exists between the molecules.

If a solvent is introduced into the resin, its molecules, being much smaller and more mobile, will move in and around the molecule of the resin. This movement in and around the resin molecule causes a physical separation by actual breaking of the secondary valence bonds. In addition, since the solvents are polar materials, they will be attracted to the attracting center on the resin macromolecule, and will compete with other resin macromolecules for these centers. This solvation is also an equilibrium process and the solvent molecule after momentary attachment is replaced by another solvent molecule or another resin macromolecule attracting center. Thus, there is a solvation-desolvation equilibrium. There are then two competing equilibria, solvation-desolvation of the solvent molecules and aggregation-disaggregation of the resin macromolecules. Obviously, a change in equilibrium in favor of solvation-desolvation would increase functionality.

Cellulose nitrate coatings



Cellulose nitrate, in order to be used as a coating material, is dissolved in a mixture of solvents. This mixture is called the thinner and is composed of liquids that have varying degrees of solvent power for the polymer. They are broadly classified as active solvents, latent solvents, and diluents. The liquids described as active solvents actually dissolve the polymer. Most of these are polar compounds containing oxygen-bearing groups. Aliphatic esters and ketones are the active solvents most commonly employed. Latent solvents are always alcohols. They do not promote solvation of the polymer by themselves. However, they usually add to the solvating effect when used in conjunction with the active solvents. Diluents are used to dilute and cheapen the thinner and are usually aliphatic and aromatic hydrocarbons.

Various tests have been developed to determine the effectiveness of a thinner as a dissolving agent. These indicate, in a practical sense, the application characteristics of such solutions. The degree of solution is indicated by the viscosity, since it is this property that indicates whether the lacquer is in a proper state of fluidity. The degree of fluidity dictates the method of application, e.g., spraying, brushing, or other techniques.

Second in importance is the tolerance of the lacquer for hydrocarbon diluents. This indicates whether the thinner has been formulated in the most economical manner. A high dilution ratio, for instance, would indicate that the thinner could stand further dilution.

Since these coatings dry by solvent evaporation, the rate of this evaporation is all-important in determining the properties of the film. Practical tests have been de-

veloped to indicate whether a thinner is evaporating properly. Determination of blush resistance of a lacquer often indicates whether or not a thinner is too fast. Blush resistance is determined by observing the degree of relative humidity at which precipitation of the film occurs. This is a function of the temperature of the film's surface as well as of the relative humidity. Therefore, a thinner that dries too rapidly will produce too great a cooling effect at the surface.

In formulating cellulose nitrate lacquers, it is generally desirable to use solvents that combine good solvent power with relatively slow evaporating properties. It is not usually easy to do this. Solvents that are most effective in reducing viscosity, such as ethyl acetate, methyl ethyl ketone, etc., also evaporate most rapidly.

Standard cellulose nitrate lacquer thinner formulations are designed to evaporate in a fairly constant manner. Thus, a graph of the evaporation rate would approach a straight line. These thinners are usually balanced with equivalent parts of fast-, medium-, and slow-evaporating solvents and diluents.

There are two major deviations from this type of formula. One is the thinner used with hot-spray lacquers. In these formulations, heat is used to aid viscosity reduction, since cellulose nitrate solvency is also a function of the temperature. Medium- and slow-evaporating solvents are used in these thinners with very little emphasis on fast evaporators.

The other deviation is classified as the "high-build thinners." In this type of formulation, only fast-evaporating solvents that are also good viscosity-reducing materials are used in conjunction with slow solvents, with little emphasis being placed in the medium boiling range. Both of these lacquers find wide acceptance in fields where the extra equipment necessary for their application is available.

Vinyl resins

Vinyl resin solutions differ from conventional nitrocellulose solutions although many of the same solvents and diluents are used in

both types. Most of the vinyl resins used for solution coatings are copolymers of vinyl chloride and vinyl acetate, with the vinyl acetate constituting about 17% of the product.

Solution coatings based on vinyl resin differ in several important ways from the conventional pyroxylin lacquers. They are less susceptible to blushing, and show greater resistance to certain solvents and to weathering. In addition, they show limited compatibility with modifying resins, possess rather poor adhesion at air-drying temperature, and have a tendency toward orange peel.

The vinyl resins used for solution coating are usually dissolved in ketones and diluted with aromatic hydrocarbon. Since blushing is not a factor and since the films are usually baked, fast-evaporating solvents can be used. Formulations are simple, compared to the highly-modified nitrocellulose lacquers. Usually, one or two vinyl copolymers and one or two solvents constitute a formula.

The solvent technology of vinyl resins also differs considerably from nitrocellulose. Solutions of high resin concentration tend to gel, as well as those in lean, thinner mixtures. These gels are not generally reversible, as are nitrocellulose gels, which merely require addition of solvent for the resin to be redissolved.

Ketones are the preferred solvents; however, nitroparaffins are also used as are some cyclic oxides. Aromatic hydrocarbons are generally preferred as the diluents. Alcohols are usually avoided in formulations containing standard vinyl copolymers.

Current developments

Developments in coating systems in which solvents are employed continue to arouse the interest of formulators. Of more recent vintage are the isocyanate lacquers. Basically, these coatings are formulated by dissolving a suitable polyalcohol and a polyisocyanate in suitable inert solvents. Inert solvents in this case are those which will not preferentially react with the isocyanates. The lower alcohols and basic solvents are not used, and solvents

containing reactive materials (water, amines, alcohols, glycols, or acids) should be avoided. Some of the pure esters such as ethyl, propyl, and butyl acetate find use as solvents in these coatings.

Polyurethane lacquers, although slow in finding popularity in this country, show promise in such applications as weatherproofing for textiles and wood; impregnants, particularly for armature windings; and corrosion-resistant coatings for metal.

Much effort has been directed toward development of systems that would obviate the need for organic solvents as a means of controlling the fluidity of resinous materials. Various mechanical systems have been devised to permit the use of heat as a fluidizing agent, and emulsion technology, in which water is the fluidizing medium, has made great strides in development. However, many types of coating application would not be feasible except from an organic solvent medium. While the physical disadvantages of solvents (toxicity, flammability, etc.,) promote investigation of substitutes, the technological advantages gained by their use should permit them to maintain their commercial importance for some time to come.

How to give your plastics the beauty of

PEARL

with

NACROMER®

Incorporated into any thermoplastic resin, or as a coating on any plastic, Nacromer adds a distinctive pearl-like lustre to any product at amazingly low cost. Either method produces excellent results—unique effects impossible to achieve any other way.

Incorporated into the plastic itself (polystyrene, polyethylene, polyesters, acetates, vinyls, etc.) Nacromer provides a pearlized effect with no changes required in your usual molding or casting process. Nacromer is easily mixed into your plastic by hand, in a Banbury, or on the rolls . . . or your compounder can supply you with ready-mixed resins containing Nacromer.

As a coating, you merely add Nacromer to your present coating material and apply by your usual method (spray, brush, or dip). No additional finishing operations are required. The addition of transparent dyes makes possible unlimited colors and effects.

Either way you use it, Nacromer will make an immediate improvement in the sales appeal of your products. Mail the coupon below for more complete information and demonstration samples.

Easier to disperse! Excellent heat and light stability!

Now, Ferro has developed a new type of reduced cadmium pigment that is lighter and fluffier for easier dispersion. New Ferro CADMOPONES are highly resistant to heat, light, acids and alkalies. They give you permanent, nonbleeding and fade-resistant colors for all plastic materials.

CADMOPONE colors are perfect for dry coloring clear resins in your own plant. This simple process eliminates waste, cuts the cost of raw materials and helps you give faster delivery on special jobs. Ferro can supply you with technical data and suggestions for dry coloring the plastics you use.

If you use red, orange or maroon in your production, you can save time and money with New Ferro CADMOPONE colors. Their faster dispersion and stability cut rejects and improve quality. Write today for color chart and samples!

Your ABC's for

INORGANIC COLORING

polystyrene

Recent developments in mold-making (i. e., pin-point gating), polystyrene in smaller sized granules or pellets, new injection molders equipped to mix clear polystyrene and color in the extruder, and new Ferro dry colors have all contributed to a quick, easy way for the polystyrene user to do his own coloring.

Write for new booklet which explains how. Also available, detailed sheets containing technical information on the use of Ferro colors with polystyrene.

polyolefin

This new high-density polyethylene resin is easily *dry colored* with Ferro pigments. Ferro has developed colors to match P. S. P. standards, as well as a line of special houseware colors for this resin.

Write for technical data sheets and procedures for dry-coloring polyolefin resins.

polyethylene

There is a trend to use polyethylene in fields where color is a necessity. The fast, easy dispersion of Ferro inorganic pigments makes them especially suitable for dry coloring this material.

Write for new booklet which gives all the facts. Technical data sheets on Ferro colors for polyethylene are also available.

nylon

A big difficulty in molding nylon is to find suitable colors that will stand up under the high temperatures required. After five years' research, Ferro has developed a line of nylon colors that is completely safe, workable and efficient.

Write for technical data sheets and new booklet which tell you how to use Ferro dry colors for nylon. A simple drum is the only equipment you need.

polyesters

Ferro paste colors are specially compounded for coloring polyester resins. They have been approved by resin users as well as the manufacturers.

A new booklet is now available to help you in polyester color work with Ferro paste colors. Write for it today.

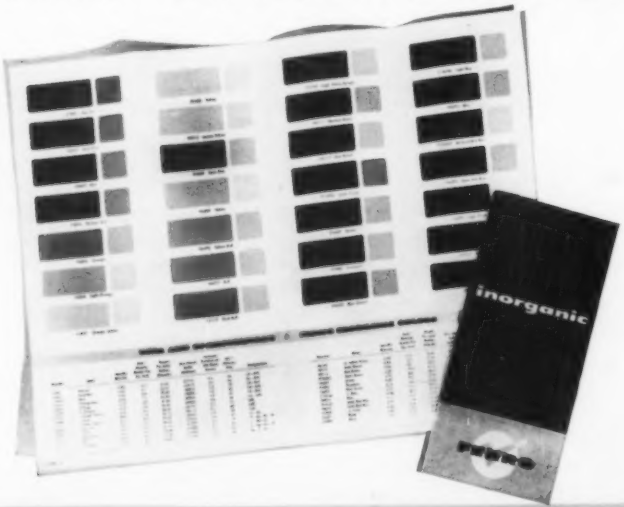
epoxies

Ferro has just developed a new group of paste colors for use with epoxy resins for casting, laminating and potting. These pastes are concentrated to give you maximum color strength per dollar. An epoxy resin is used as the liquid medium to solve problems of incompatibility.

vinyls

Many dry colors are not adaptable to vinyl formulas because of the hardness of the colors, or because colors contain zinc or iron. Ferro dry colors produce a soft, non-specking color and colors may be selected that contain no zinc or iron.

New booklet points out advantages of dry coloring over color concentrates, and describes best method of dry coloring for calendering, extrusion, molding. Send for it, today.



fluorothene . . . Kel-F . . . Teflon

Fabricated at temperatures up to 700°F., these fluorine-type resins require colors of high heat stability. In some instances, it is also necessary to pulverize the color-resin mixtures (in the case of Teflon, after cooling to sub-zero temperatures).

Write for new booklet which describes the techniques involved, also tells how to select Ferro colors for best results.

WRITE ALSO FOR THESE BOOKLETS:
Technique of Coloring Lucite and Plexiglas . . . Technique of Coloring Cellulose Acetate and Cellulose Acetate Butyrate

FERRO INORGANIC BASE PIGMENTS

it will pay you to specify colors by Ferro because . . .

- Ferro pigments are finely ground mixtures of inorganic materials calcined from 1200° to 2300° F. They blend readily; are easy to work; have a low bulking value.
- Ferro pigments are resistant to acids, alkalies, all weather conditions; are heat- and light-fast, and non-migrating.
- Ferro maintains a color-matching service. Any desirable color can be "tailored" to the vehicle designated by the customer.
- Ferro pigments are checked and then double checked under the customer's production conditions. When Ferro pigments leave our plant, they're "right"—ready for use.

write today for new combination Inorganic Color Chart and Data Sheet. Shows Ferro's 28 Base Colors with which almost any desired color match can be made.

Admex VINYL PLASTICIZERS

Nation Wide in Service

Industry Wide in Performance

ADMEX EPOXY PLASTICIZERS

Admex 710 Double duty . . . serves as both plasticizer and stabilizer. For compounding film and sheeting, plastisol and organosol dispersions and extruded products. Insures color uniformity of consumer products when exposed to constant sunlight and high temperatures.

Admex 711 Resistance to migration and exudation exceeds any other commercially available plasticizer of its type. For film, sheeting, coated fabrics, floor tile.

Admex 744 For outstanding performance at temperature extremes. Provides low temperature flexibility. Contributes color stability to compounds requiring high heat processing.

Admex 745 A new low temperature plasticizer with low volatility and extraction features.

ADMEX POLYMERIC PLASTICIZERS

Admex 760 New pale colored polymeric having outstanding permanence and non-migration.

Admex 761 Versatile polymeric of low viscosity and with maximum extraction resistance.

UVINUL®

400, 490, D49, M40

Permanently Prevent Deterioration and Discoloration caused by Ultraviolet Light

Versatile Uvinul absorbers and stabilizers have many profitable applications to the plastics industry. They can be incorporated into solid plastics and protective coatings to permanently prevent deterioration and discoloration caused by ultraviolet radiation. They are also effective as stabilizers for organic liquids and aqueous solutions.

The Uvinul stabilizers offer a full range of compatibilities and ultraviolet protection permitting users to select the product best suited for their needs. Write today for more detailed information.

GODFREY L. CABOT, INC.

77 FRANKLIN STREET, BOSTON 10, MASSACHUSETTS

From one dependable source . . .
a complete range of organic chemicals for the plastics industry

National Aniline is the leading supplier of organic chemicals for resins, plasticizers and plastics.

Our complete line of dibasic acids, anhydrides and related chemicals . . . already the broadest range available . . . answers the plastic industry's need for a diversity of basic materials.

Production facilities are ample to meet the constantly expanding volume. Continuing supply is assured from our long-established facilities at Buffalo, N. Y. and our ultra-modern plants recently constructed at Hopewell, Va. and Moundsville, W. Va.

Technical data and samples of the products described and listed here are available. We will be glad to quote prices and delivery.

National Aniline Allied Chemical

NACCONATES®
(Diisocyanates)

Urethanes are so versatile that the ultimate limits of their usefulness and their market potential have yet to be predicted. As major producers of diisocyanates, National Aniline is prepared to meet the foreseeable demand with integrated production from a new multi-million-dollar plant at Moundsville. Technical Bulletin I-17, supplements A to F and product data sheets are available on request.

MALEIC ANHYDRIDE
Tablets

National Maleic Anhydride tablets set the standard for the resin-chemical industry. They are uniform, easier to handle, quick-dissolving, essentially non-dusting and have few fines. Mixed car and truckloads are offered with Phthalic Anhydride, Fumaric and Adipic Acid. Comprehensive data on Maleic Anhydride is contained in our 58-page book, and we will gladly submit samples, specifications and prices.

PHTHALIC ANHYDRIDE

The standard of quality for the industry is set by National Phthalic Anhydride. Available in molten and flake form. Mixed car and truckloads are offered with Maleic Anhydride, Adipic and Fumaric Acid. Working samples sent on request.

NADONE*
(Cyclohexanone)

Fully-integrated production of the highest-quality cyclohexanone available! Produced at Hopewell by an advanced, direct, continuous process with a minimum purity of 99.0%, NADONE makes high-quality, light-colored resins. A sample will show you how good it is. Technical Bulletin I-19 gives properties, reactions and an inclusive bibliography.

ADIPIC ACID

Basic, non-captive production by an efficient, continuous process makes National Aniline a major supplier. National Adipic Acid analyzes at least 99.8% in purity and is light in color, low in iron. For complete product information request Technical Bulletin I-12.

NAXOL*
(Cyclohexanol)

Substantial basic production of this important secondary alcohol is now on stream and can be quickly expanded to meet any foreseeable need. Two types immediately available: NAXOL (100% material) and NAXOL D (freezing point depressed). Working samples available. We will be glad to quote price and delivery on C/L and LCL quantities.

FUMARIC ACID

Produced at Moundsville and Buffalo by a direct process developed by National Aniline research, National Fumaric Acid is unequalled anywhere. 99.6% pure and free-flowing. Its absence of color makes it extremely useful for resins and plasticizers.

Mixed car and truckloads available with Maleic Anhydride, Phthalic Anhydride and Adipic Acid. Samples and quotations on request.

ε-CAPROLACTAM

This unusual 6-carbon chemical is in large-scale production at Hopewell. Ample supplies are available at an attractive price. We will gladly provide working samples and technical assistance leading to the development of new applications. Technical Bulletin I-14 describes known chemical reactions, suggesfed uses and bibliography.

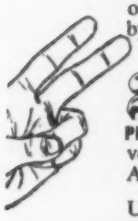
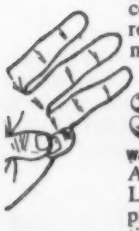
you save 3 ways with BROWN-ALLEN plasticizers



1 **Don't sacrifice quality in your vinyl formulations!** Don't use inadequate secondary plasticizers! Get a primary plasticizer—Polycon #40 (a pure phthalate) at the economy level.

Polycon #40 was developed for use in vinyl flooring, welting, garden hose and other extruded vinyls where slight plasticizer coloration is acceptable. Polycon #40 is also used in coated fabrics, slush and dip moldings, wire and cable coverings.

BROWN-ALLEN Polycon #40's features make it ideal for extrusion compounds. Among these features are:



- Superior solvation
- Excellent toleration for low-cost plasticizer extenders
- Gelation and cure rates that help increase production in plastisols
- Greater toleration of filler loads

In addition, BROWN-ALLEN Polycon #40 offers a higher electrical resistivity than DOP by actual test on compounded products.

2 **For a low-cost replacement for n-Octyl n-Decyl Phthalates** where low temperature and low volatility are desirable, look into BROWN-ALLEN Polycon #5B.

Used in plastisols, BROWN-ALLEN Polycon #5B offers improved flow-out properties, slow gelation and fast cure in addition to low viscosity and excellent viscosity stability. This results in superior definition in complex molds.

3 **Whether you buy plasticizers in drums, tank wagons or tank cars,** find out about BROWN-ALLEN DOP, DIOP, ODP, DBP and DDP. Like all BROWN-ALLEN products, these plasticizers are precisely uniform, competitively priced and of dependably high quality.

NOW! Use CHLOROWAX 70 for low-cost flame-retardant polyesters

DIAMOND's Chlorowax® 70 is a powdered resin containing 70% chlorine. Use it together with antimony trioxide in pigmented polyester resin formulations and you can produce low-cost flame-retardant polyesters that will still retain *physical properties comparable to straight resin.*

EXAMPLE

	(Parts by Weight) Control	Flame Retardant
Polyester Resin	100.00	100.0
Chlorowax 70	—	12.5
Antimony Trioxide	—	12.5
Luperco ATC	2.0	2.0
Colored Pigment	as required	
3-oz Glass Mat	60.0	60.0
Flexural Strength psi, Dry 1	26,000	27,500
Flexural Strength psi, Wet 2	24,000	25,000
Tensile Strength psi, Dry 3	15,000	15,700
Tensile Strength psi, Wet	14,000	14,300
Flame-Out Time, Seconds 4	Burns	1

METHODS OF TESTING

1. Flexural Strength — ASTM-D650-42T
2. Water Immersion — 7 days immersion at room temperature
3. Tensile Strength — ASTM-D638-46T
4. Flammability Test — ASTM-D635-44 — Test specimen 1″ x 6″ x 3/32″ is suspended horizontally at 45 degree angle so that 1″ of the specimen is exposed in a 5″ (1-1/2″ blue core) flame from a Bunsen burner. The sample is exposed 30 seconds and then the flame is removed. To be classed flame resistant the sample must be self extinguishing in less than 20 seconds.

For more information about moneysaving Chlorowax 70, send for NEW Technical Bulletin on "Low-Cost Flame-Retardant Pigmented Polyester Compounds". DIAMOND ALKALI COMPANY, 300 Union Commerce Building, Cleveland 14, Ohio.

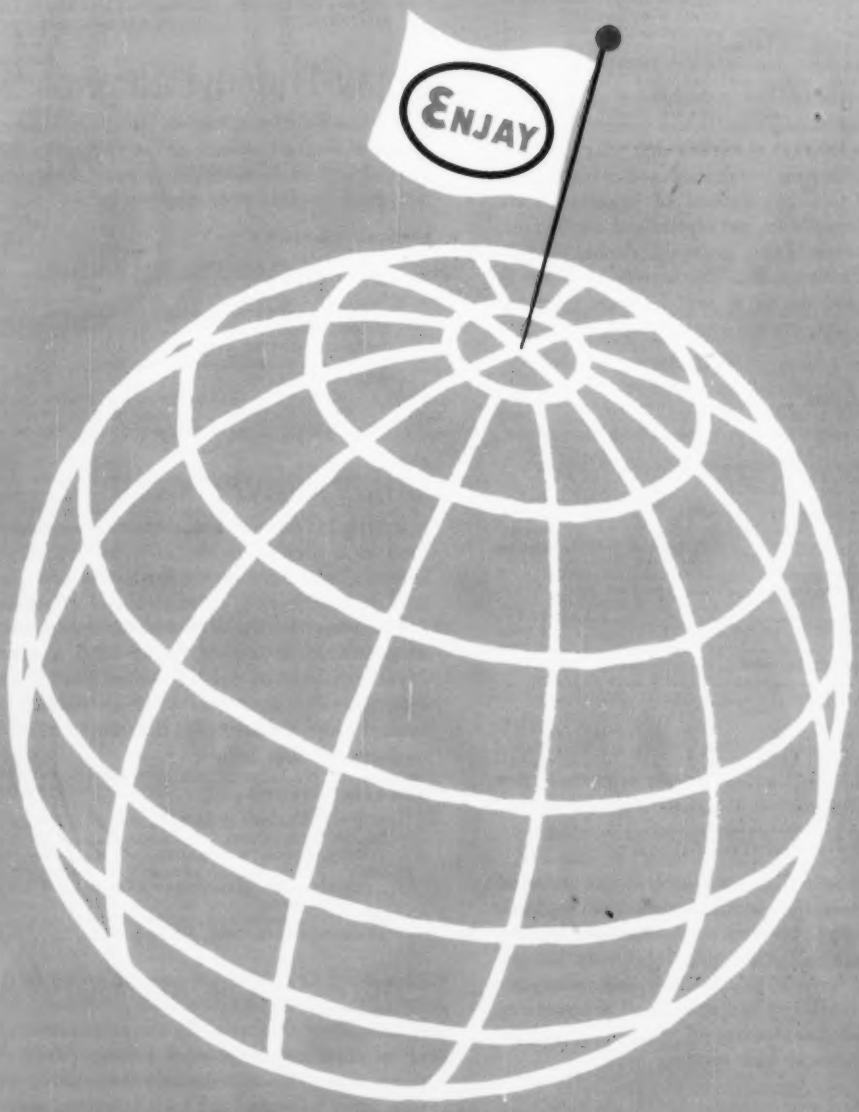
How to figure your sales potential in the plastics field



FREE . . . 40-page brochure will help you find answers to your questions about sales opportunities in the fast-growing plastics field.

THIS NEW STUDY contains the inside story of one of America's fastest growing industrial markets. It presents one of the most stimulating and detailed analyses of the plastics field that has yet been published. It's filled with up-to-date figures on the consumption and production of plastics materials, on the field's processing equipment requirements, on potential areas of growth. It lists hundreds of kinds of machines, accessories, chemicals and intermediates, supplies and special services for which the field is manifesting an ever-increasing appetite.

You will find this handsome brochure—file size, lavishly illustrated, 40-pages—a valuable addition to your business library. It may well point the way to increased sales for the industrial products or services that your firm supplies.

For your free copy of "The Plastics Field," simply address a note on your company letterhead to *Advertising Manager*, Modern Plastics, 575 Madison Avenue, New York 22.

ALCOHOLS

Enjay Isopropyl Alcohol

is a valuable raw material for the manufacture of chemical derivatives such as acetone and esters. It is a solvent for many oils, resins and surface coating materials and may be used readily in extraction processes, cosmetics and varnish and lacquer formulations. Other applications of importance are anti-freeze, cleaning compositions, antiseptics and astringents, insecticides and disinfectants. Enjay isopropyl alcohol is available in 91% and anhydrous grades. The anhydrous grade is unique in its dryness and purity as will be seen from the following specifications and typical inspections.

SPECIFICATIONS

WATER, weight per cent, max.	0.15
SPECIFIC GRAVITY, 20/20°C, max.	0.7867
ACIDITY, as acetic acid, weight per cent, max.	0.002
COLOR, Hazen, max.	10
NON-VOLATILE MATTER, mg/100 ml, max.	2
DISTILLATION, °C	
Initial, min.	81.5
Dry point, max.	83.0
RESIDUAL ODOR	none
WATER DILUTION	Clear at infinite dilution

TYPICAL INSPECTIONS

Purity, volume per cent	99.9+
Specific gravity, 20/20°C	0.7866
60/60°F	0.7823
Acidity, as acetic acid, weight per cent	0.001
Color, Hazen	5
Non-volatile matter, mg/100 ml	1
Distillation, °C	
Initial	81.8
Dry point	82.4
Residual odor	none
Water dilution	Clear at infinite dilution

Enjay Isooctyl Alcohol

is a versatile raw material for the manufacture of chemical derivatives such as esters, isooctyl aldehyde and isooctoic acid. Di-isooctyl phthalate is a widely used plasticizer for synthetic resins such as vinyls. Other uses for Enjay isooctyl alcohol are as a solvent for oils, gums, waxes and resins, and as a coupling agent in emulsions and soluble oil concentrates, and as a solvent in the manufacture of greases, insecticide concentrates, textile lubricants and printing inks.

SPECIFICATIONS

PURITY, weight per cent, min.	99.0
SPECIFIC GRAVITY, 20/20°C, min.	0.830
max.	0.834
ACIDITY, as acetic acid, weight per cent, max.	0.001

WATER, weight per cent, max.	0.10
CARBONYL NUMBER, mg KOH/g, max.	0.3
DISTILLATION, °C	
Initial, min.	184
Dry point, max.	191

Enjay Decyl Alcohol

is widely used in the manufacture of ester plasticizers such as didecyl phthalate and didecyl adipate as well as for co-esters such as isooctyl-decyl phthalate. Other uses for Enjay decyl alcohol are in the manufacture of anti-foaming agents, textile lubricants and herbicides.

SPECIFICATIONS

PURITY, weight per cent, min.	99.0
SPECIFIC GRAVITY, 20/20°C, min.	0.835
max.	0.840
ACIDITY, as acetic acid, weight per cent, max.	0.001

DISTILLATION, °C	
Initial, min.	245
Dry point, max.	270
APPEARANCE	Bright and clear, free from suspended matter

Enjay Ethyl Alcohol

is a valuable solvent and chemical raw material. It is widely used as a solvent in the manufacture of shellac varnishes, lacquers, pharmaceuticals, cosmetics and plastics. It is also used in purification, extraction and crystallization processes. It has many important uses in the synthesis of a wide variety of chemical compounds. Enjay ethyl alcohol is available as Jaysol (proprietary solvent) as well as in specially denatured formulas. The properties of these alcohols are available on request. The specifications for Enjay ethyl alcohol used in their preparation follow.

SPECIFICATIONS

SPECIFIC GRAVITY @ 60/60°F, max.	0.8160

PERMANGANATE TIME, minutes, min.	30

Enjay Secondary Butyl Alcohol

is a useful raw material for the preparation of chemical derivatives such as methyl ethyl ketone, esters, chloride and xanthate. Due to its intermediate evaporation rate, compatibility with other solvents, and high solvency, secondary butyl alcohol has wide application in the formulation of varnishes and lacquers.

SPECIFICATIONS

SPECIFIC GRAVITY, 20/20°C, min.	0.807

OLEFINS

Enjay Isobutylene

is a versatile, high purity chemical usable in a variety of syntheses. In addition to the normal olefin reactions, it may

be di[illegible]ized to isooctylenes or used in the alkylation of tertiary [illegible]raffins, aromatics, or phenols. Hydration yields tertiary [illegible]tyl alcohol. Reaction with oxides of nitrogen or nitrosyl [illegible]loride produces compounds of possible interest for the s[illegible]thesis of nitrogen derivatives.

SPECIFICATIONS

PURITY, weight per cent, min.	99.0
BUTENES, weight per cent, max.	0.8
BUTANES, weight per cent, max.	0.5
CARBONYL, as acetone, weight per cent, max.	0.01
SULFUR, ppm, max.	10
WATER, weight per cent, max.	0.007
DISTILLATION, °C, weight per cent below −15°, max.	0.05

Enjay Tripropylene

is an excellent source of 9-carbon olefins useful in ordinary olefin reactions as well as in alkylation of aromatics and phenols for the manufacture of detergents and resin intermediates.

SPECIFICATIONS

UNSATURATES, volume per cent, min.	97.0
SPECIFIC GRAVITY, 20/20°C, min.	0.733
max.	0.743

PEROXIDES, active oxygen, ppm, max.	25
INHIBITOR, tertiary butyl catechol, ppm, min.	100

Enjay Tetrapropylene

is a primary source of 12-carbon tertiary olefins and responds to the general olefin reactions. It is a valuable raw material for the production of detergent intermediates such as dodecyl benzene. With hydrogen sulfide, it yields a mercaptan usable in the manufacture of synthetic rubber.

SPECIFICATIONS

UNSATURATES, volume per cent, min.	98.0
SPECIFIC GRAVITY, 20/20°C, min.	0.770
max.	0.785
DISTILLATION, °F	
Initial, min.	350
Dry point, max.	430
PEROXIDES, active oxygen, ppm, max.	20
INHIBITOR, U.O.P. No. 5-lbs/1000 bbls, min.	4

Nonene (Close Cut)

is a source of high-purity nonenes applicable in the manufacture of detergent and resin intermediates through alkylation and yielding products with closely controlled physical and chemical properties. Nonene is a potential source for a great variety of higher olefin derivatives.

SPECIFICATIONS

UNSATURATES, volume per cent, min.	99.0
SPECIFIC GRAVITY, 20/20°C, min.	0.736
max.	0.740
DISTILLATION, °F	
Initial, min.	260
Dry point, max.	290

PEROXIDES, active oxygen, ppm, max.	25
INHIBITOR, tertiary butyl catechol, ppm, min.	100
APPEARANCE,	Bright and clear, free from suspended matter

DIOLEFINS

Enjay Butadiene

is a highly reactive, high purity diolefin which takes part in many reactions. It may be polymerized by itself or copolymerized with products such as styrene or acrylonitrile to yield resins and plastics. The styrene copolymer is the base of many water emulsion paints and of synthetic rubber. Butadiene reacts with maleic anhydride and its esters to yield cyclohexene dicarboxylic acids and their derivatives.

SPECIFICATIONS

CONJUGATED DIENE, as 1,3 butadiene, weight per cent, min.	98.0
ACETYLENES, as vinyl acetylenes, ppm, max.	500
CARBONYL, as acetaldehyde, ppm, max.	100
PEROXIDES, as hydrogen peroxide, ppm, max.	10
SULFUR, as hydrogen sulfide, ppm, max.	10
BUTADIENE DIMER, weight per cent, max.	0.2
HYDROCARBONS, (C_5), weight per cent, max.	0.1
NON-VOLATILE MATTER, weight per cent max.	0.1
OXYGEN IN VAPOR OF FILLED CAR, volume per cent, max.	0.3
INHIBITOR, tertiary butyl catechol, ppm, in tank car as loaded by consignor	100
APPEARANCE,	Clear and free of entrained matter

Enjay Isoprene

is a highly reactive diolefin similar in properties and reactions to butadiene and yielding generally the same types of derivatives. It is assuming an increasing importance as raw material for the manufacture of "synthetic natural rubber."

SPECIFICATIONS

ISOPRENE, weight per cent, min.	92.0
TOTAL DIOLEFINS, weight per cent, min.	95.0
CYCLOPENTADIENE, weight per cent, max.	1.0
ALPHA ACETYLENES, as isopropyl acetylene, weight per cent, max.	0.70
CARBONYL, as acetone, ppm, max.	100
SULFUR, ppm, max.	100
PEROXIDES, as hydrogen peroxide, ppm, max.	10

Enjay Dicyclopentadiene

is the source for the unique and highly reactive cyclopentadiene which is generated by heating dicyclopentadiene. Cyclopentadiene undergoes most of the reactions of normal diolefins and in addition may be converted to organo-metallic derivatives and mono- and di-carboxylic acids. With maleic anhydride, cyclopentadiene yields a dibasic acid. Cyclopentadiene monocarboxylic acid on reaction with maleic anhydride gives a tribasic acid. Dicyclopentadiene is a fruitful source for new chemicals.

SPECIFICATIONS

DICYCLOPENTADIENE, weight per cent, min.	95.0
DI(METHYL CYCLOPENTADIENE), weight per cent, max.	3.5
ACYCLIC DIENES, weight per cent, max.	2.5
HIGHER CYCLIC DIENES, weight per cent, max.	0.3
SPECIFIC GRAVITY, 20/20°C, min.	0.970
max.	0.985
COLOR, Gardner, max.	1.0
INHIBITOR, ppm, max.	250
APPEARANCE,	Clear and free of entrained matter

KETONES

Enjay Acetone

is a valuable solvent and chemical raw material in industry. It is used as a solvent for acetylene and for cellulose acetate for the manufacture of a wide variety of surface coating compositions and in industrial extraction processes. Acetone is a raw material for chemical derivatives such as chloroform, iodoform, isophorone, ketone and acrylic resins.

SPECIFICATIONS

SPECIFIC GRAVITY, 20/20°C, min.	0.791
max.	0.793
ACIDITY, as acetic acid, weight per cent, max.	0.002
COLOR, APHA, max.	5
WATER DILUTION, with distilled water	Clear
DISTILLATION, °C	
Initial, min.	55.5
Dry point, max.	56.5
NON-VOLATILE MATTER, mg/100 ml., max.	1.0
PURITY, weight per cent, min.	99.5
PERMANGANATE TEST, hours, min.	2.0
WATER	Clear with 19 volumes naphtha

Enjay Methyl Ethyl Ketone

is an efficient solvent for vinyl and other synthetic resins, nitrocellulose, cellulose acetate and buna-N type rubbers. Because of its solvent properties, it is employed in the manufacture of nitrocellulose cements, artificial leathers and fabric coating and photographic film. Methyl ethyl ketone in combination with benzol or toluene is used to reduce the wax content of lubricating oils. It is only partially miscible with water. The evaporation rate of methyl ethyl ketone is lower than that of acetone and is comparable to that of ethyl acetate.

SPECIFICATIONS

SPECIFIC GRAVITY, 20/20°C, min.	0.805
max.	0.807
COLOR, Hazen, max.	10
ACIDITY, as acetic acid, weight per cent, max.	0.002
DISTILLATION RANGE °C, including 79.6	1.5
NON-VOLATILE MATTER, mg/100 ml., max.	2.0
PURITY, weight per cent, min.	99.0
RESIDUAL ODOR	none
WATER, weight per cent	0.2

ACETATES

Enjay Isopropyl Acetate

is a low-cost lacquer solvent which has properties similar to ethyl acetate. It evaporates more slowly than ethyl acetate and, therefore, is valuable for blush-resistant formulations. Isopropyl acetate has good solvent properties which suggest a wide use in chemical industries.

SPECIFICATIONS

SPECIFIC GRAVITY, 20/20°C, min.	0.868
max.	0.872
COLOR, APHA, max.	5
ACIDITY, as acetic acid, weight per cent, max.	.01
DISTILLATION, °C	
Initial, min.	85.0
Dry point, max.	90.0
NON-VOLATILE MATTER, mg/100 ml., max.	2.0
PURITY, weight per cent, min.	95.0
RESIDUAL ODOR	none
WATER	Clear with 19 volumes naphtha

Enjay Secondary Butyl Acetate

is a medium boiling solvent used in the manufacture of nitrocellulose coatings, films and plastic products from many resins. It may replace blends of ethyl and normal butyl acetates and is particularly useful in the formulation of lacquer "sealers." Secondary butyl acetate dissolves manila, mastic, pontianak, ester, and other gums and asphalt and is miscible with vegetable oils. It is a partial solvent for shellac and does not dissolve cellulose acetate.

SPECIFICATIONS

SPECIFIC GRAVITY, 20/20°C, min.	0.861
max.	0.865
COLOR	water white
ACIDITY, as acetic acid, weight per cent, max.	.02
DISTILLATION, °C	
Initial, min.	104
Dry point, max.	115
NON-VOLATILE MATTER, mg/100 ml., max.	2.0
PURITY, weight per cent, min.	87
max.	90
RESIDUAL ODOR	none
WATER	Clear with 19 volumes naphtha

ETHERS

Enjay Ethyl Ether

is a standard solvent for fats, oils, waxes, gums, resins and nitrocellulose. It is useful in making rayon and pyroxylin compositions and as a solvent for extraction processes.

SPECIFICATIONS

SPECIFIC GRAVITY, 20/20°C, min.	0.712
max.	0.720
ACIDITY, as acetic acid, weight per cent, max.	0.005
ALCOHOL, weight per cent, max.	1.0
NON-VOLATILE MATTER, mg/100 ml., max.	0.002
WATER, weight per cent, max.	0.25
INHIBITOR, alpha naphthol, added, ppm.	85
COLOR, Hazen, max.	10

OTHER ENJAY PRODUCTS: Enjay also offers benzene, p-xylene, CTLA polymer, naphthenic acids, aromatic tars and distillates and wood-preserving solvents. For further information on these or other Enjay products—and for samples, supplies or technical assistance—call or write any Enjay office.

NEW ENJAY LABORATORIES OFFER TECHNICAL HELP IN THE APPLICATION OF ANY ENJAY PRODUCT

The new Enjay Laboratories, with the industry's most modern, most complete testing and research facilities, stand ready to give you any technical assistance you might need in the application of any Enjay petrochemical.

There's one way to be SURE!

Make your products with

COLUMBIAN

Pigments, Colloidal Dispersions and Plasticizers

COLUMBIAN CARBON BLACKS

Carbon Blacks are indispensable elements of color in many plastics. Especially useful in plastics are: Neo Spectra® Mark II and III, Superba®, No. 999 and Raven® 15. The degree of jetness obtained depends on the particle size of the carbon and its degree of dispersion. In polyethylene pipe and cable sheathing carbon black protects from sun damage. Whatever your need, Columbian has a carbon black to fit it.

COLUMBIAN COLLOIDAL DISPERSIONS

Complete dispersion is a prerequisite of depth of color. Many manufacturers have found profitable satisfaction in using Columbian Colloidal Dispersions of carbon blacks. These complete dispersions in any vehicle give greatest jetness and THEY ARE CLEAN to handle and use. They produce jet black plastics with ease; and predispersed color needs only mixing, no grinding.

COLUMBIAN MAPICO® IRON OXIDES

A wide range of beautiful and notably uniform yellows, tans, reds, browns and black, these pure synthetic iron oxide pigments possess excellent alkali and acid stability, extreme light-fastness, and valuable ultra-violet screening characteristics. Useful in vinyls, polyethylene, polystyrene, polyesters; for flooring, sheeting, coated textiles, toys, dolls, mats, footwear, insulation compounds and others.

PLASTICIZERS

Latest in plasticizing dependability, the new POLYMERIC type is outstanding for easy processing and permanence. Use Harflex 300 or 325. The results will surprise you. Other Plasticizers — PHTHALATES, SEBACATES, ADIPATES — include the low-temperature, low-volatile, low-water-soluble DIOCTYL SEBACATE and DICAPRYL PHTHALATE.

Our Technical Service Department is always ready to assist you.

COLUMBIAN CARBON COMPANY

380 Madison Avenue, New York 17, N.Y.

BASIC REASONS FOR

CELANESE

PLASTICIZERS

CELLUFLEX 179-A (Tricresyl Phosphate, low ortho content) — contains lowest ortho content commercially available. Useful as a flame-resistant plasticizer, particularly in cellulosics and vinyls.

CELLUFLEX 179-EG (Tricresyl Phosphate, electrical grade)—affords the insulation industry excellent solvent properties and inherent flame resistance with uniform high electrical characteristics and lower weight per unit volume.

CELLUFLEX 179C (Tricresyl Phosphate, general purpose grade)—combines excellent solvent power and flame retardant properties as general plasticizer for vinyl resins and cellulosic plastics. Especially advantageous for coatings and films where extreme flame resistance and toughness are vital.

LINDOL (Tricresyl Phosphate, low color)—a standard flame-resistant plasticizer in vinyl and cellulosic plastics.

CELLUFLEX 112 (Cresyl Diphenyl Phosphate)—useful in achieving a high degree of flame resistance in vinyl formulations with better low temperature properties than can be reached with tricresyl phosphate.

CELLUFLEX TPP (Triphenyl Phosphate)—most widely used plasticizer in cellulose acetate. Provides excellent fire resistant properties, good flexibility; produces clear tough compositions.

CELLUFLEX DBP (Dibutyl Phthalate)—excellent light and heat stability, low viscosity plasticizer. Most widely used plasticizer for cellulose nitrate lacquers and coatings. Produces good gloss, high flexibility.

CELLUFLEX DOP (Dioctyl Phthalate)—low volatility, excellent heat and light stability, superior electrical properties. Primary plasticizer for vinyl resins, synthetic rubber in cloth coatings, elastomeric molded materials.

CELLUFLEX CEF (Trichloroethyl Phosphate)—flame-retardant with excellent plasticizing properties. Widely used with polyurethane, phenolics, cellulosics and polyvinyl acetate. Secondary plasticizer for polyvinyl chloride.

LINDOL® CELLUFLEX®

TECHNICAL SERVICE

If you are limited by space and time, experienced chemists in the fully-equipped CELANESE TECHNICAL SERVICE AND APPLICATION LABORATORIES will be glad to assist you in the development of new and improved formulations. Trial lots will be subjected to specified tests and production costs analyses prepared.

IMPROVED PRODUCTS

CELANESE

INTERMEDIATES

ACETIC ACID (Glacial)—reactant and solvent in manufacture of cellulose acetate.

ACETIC ANHYDRIDE — acetylating agent used primarily for the esterification of cellulose to cellulose acetate.

BUTYRIC ACID—used in manufacture of cellulose acetate-butyrates for molded products, lacquers, weatherproof coatings.

FORMALDEHYDE (Formalin) — reacts with phenol, urea and melamine to form plastics and resinous products.

FORMCEL SOLUTIONS — relatively water-free formaldehyde solutions in selected alcohols. Starting materials for production of alcoholated condensation resins.

METHYL ISOPROPENYL KETONE—new vinyl monomer which forms tough plastics in homopolymerization and copolymerizes with many commercially available vinyls for use as plastics, films, elastomers and adhesives.

PARAFORMALDEHYDE—low water content formaldehyde (91% assay as formaldehyde) in solid form, used in production of urea and phenolic resins for greater efficiency in cycle time, yield and production costs.

P. E. (Pentaerythritol)—used in manufacture of medium and long oil alkyd resins, to produce surface coatings with higher gloss retention, faster drying time, increased durability. Also used in production of rosin esters and synthetic drying oils.

PROPIONIC ACID—used for production of cellulose propionate, a molding powder exhibiting superior impact strength and aging characteristics.

VINYL ACETATE MONOMER — basic material in manufacture of polyvinyl resin adhesives, textile and paper coatings, plastic films, sheeting and molding materials, water-emulsion paints.

Celanese® CHEMICALS

In these five Standard Units are all the necessary components to control effectively the degradation mechanisms that take place in polyvinyl chloride resins on aging, during heat processing or on exposure to sunlight. They are widely used alone and in combinations for specific effects in clear and opaque stocks. Their advantages have been proven over other tested materials, such as those based on tin (which frequently decolorizes effects of degradation without correcting them) or on lead (which frequently contributes to oxidation and breakdown on aging). To correct special conditions encountered in each Vinyl Processing Industry, we also supply combinations of selected components in these five Standard Units.

Write for information about stabilizers designed for versatile and inexpensive use in formulations employed in your particular vinyl processing industry.

Is it for—

Quality Vinyl Flooring?
Non-Plating Calendered Stocks?
Maximum Clear Sheets?
Non-Sulfur Staining Films?
Low Cost Clear & Opaque Hose?
Top Physical Properties in Rigids?
Air-Releasing Plastisols?
Controlled Slush Molding?

This Stabilizer System is for

Vinyl Flooring

HARSHAW PIGMENTS

INORGANIC PIGMENTS

Harshaw Pigments find widespread application in industry, especially where an inorganic type of pigment is desirable, such as in automobile and sign enamels and lacquers, permanent inks, resin and latex emulsion paints, plastics, artificial leather, fire-retardant coatings, rubber goods, wallpaper and artists colors. Wherever they are used, Harshaw colors show outstanding brilliance, strength and light fastness.

Yellows... Cadmium Lithopones and C. P. Cadmium Pigments—Primrose, Lemon and Golden
Sun Yellow N and C—extremely durable pastel yellow pigments (Nickel titanium dioxide complex.)

Oranges.. Cadmium Lithopones and C. P. Cadmium Pigments—Orange and Orange Red

Reds..... Cadmium Lithopones and C. P. Cadmium Pigments—Light Red, Medium Red, and Dark Red

Maroons.. Cadmium Lithopones and C. P. Cadmium Pigments—Maroon and Dark Maroon

Blues..... Cobalt Blue and Cerulean Blue

White.... Antimony Oxide

Other Colors and Pigments

Harshaw also offers a broad line of organic pigment colors, as well as a full line of Aurasperse organic and oxide dispersions. The dry colors are for general color uses, while Aurasperse dispersions find application in emulsion plant formulations.

IN THERMOPLASTICS

by Reed

GIVES YOU 3-WAY ASSURANCE OF PERFECT RESULTS

Special effects "unlimited" . . . opaque, transparent, translucent, opalescent, pearlescent, metallic, fluorescent, *any* effect you desire. We have built our reputation by solving difficult coloring problems of every type.

Service plus! Samples and production can be manufactured to your specifications and, in many cases, shipped to your plant overnight.

Quality without question! We have the largest staff of experienced chemists and the most modern thermoplastics laboratory in the industry.

Matching of colors is a REED specialty. We welcome an opportunity to match your samples!

Reed Plastics Corporation

Yours for the asking!

The companies that supply the equipment, resins, chemicals, molding compounds and services used in the manufacture of plastics products turn out a continuing stream of valuable and informative bulletins, catalogs, manuals, and technical reports. Much of this material is offered without charge to interested businessmen.

You'll find brief descriptions of about four dozen pieces of such literature on the Manufacturers' Literature Page of each monthly issue of *Modern Plastics* magazine . . . and on the same page you'll find a detachable prepaid postcard on which you can order the specific items you want—*free.*

Next issue you get, turn to the Manufacturers' Literature Page . . . and use it!

GRAMERCY 5-1030

	DESCRIPTION	USE
BARIUM		
ADVASTAB B-13-P	Liquid Barium Organic Complex containing Auxiliary Stabilizers	In combination with Z-6 in processing of calendered products, extrusion and p[illegible]sols, where resistance to sulfide staining is a prime necessity. Also in vinyl asbestos til[illegible]
BARIUM-CADMIUM (Powder)		
ADVASTAB BC-12	Co-precipitated Barium-Cadmium-Laurate	General purpose heat and light stabilizer providing lubrication, exceptionally [illegible]ted when a powdered material is desired.
BARIUM-CADMIUM (Liquid)		
ADVASTAB BC-74	Barium-Cadmium Chelate Complex	A liquid system for all types of processing where lubrication is **not** desired. Gives maximum clarity obtainable from a Barium-Cadmium system. Excellent light stability.
ADVASTAB BC-105	Barium-Cadmium Chelate Complex	Plastisols, organosols and chemically blown sponge. Rigids (with C-79 and CH-201) where clarity and long term stability are imperative. In calendered stock to minimize plate-out.
BARIUM-ZINC		
ADVASTAB BZ-51	Barium-Zinc Chelate Complex	Completely eliminates sulfide staining under all processing conditions. Using BZ-51 in conjunction with BC-74, BC-105 or C-79 maintains stain resistance with maximum heat stability.
ADVASTAB BZ-155	Co-precipitated Barium-Zinc Soap	Specifically designed for calendering, extrusion and floor tile. Provides lubrication with complete resistance to sulfide staining.
CADMIUM		
ADVASTAB C-79	Liquid Cadmium containing Auxiliary Stabilizers	For garden hose, tubing, film and sheeting, where maximum resistance to water absorption is essential, and where clarity is important to the consumer market.
AUXILIARIES		
ADVASTAB CH-101	Non-metallic Organic Auxiliary Stabilizer	Extends the heat cycle for safe processing and aids in obtaining clarity. An auxiliary stabilizer for all primary metallic stabilizers including lead. Powerful anti-oxidant.
ADVASTAB CH-201	Non-metallic Organic Auxiliary Stabilizer	Extends the heat cycle for safe processing and aids in obtaining clarity. Preferred over CH-101 where no Epoxy Plasticizer is included.
ZINC		
ADVASTAB Z-6	Liquid Zinc containing Auxiliary Stabilizers	Used only in conjunction with Advastabs B-13-P, BC-12, BC-74 or BC-105 for maximum heat and light stability together with minimum sulfide staining.
EPOXY		
ADVASTAB E-82	Concentrated Epoxy-type Stabilizer	Extends performance of primary stabilizers, thus giving improved long-term heat stability. Particularly suited in systems containing zinc stabilizers or phosphate plasticizers.
ORGANO-TIN		
ADVASTAB T-52	Complex Organo-Tin Compound in Plasticizer Carrier	For clarity, brilliance and light resistance in calendered film and plastisols. For garden hose, tubing and film where water resistance is imperative.
ADVASTAB T-52-N	Complex Organo-Tin Compound in Plasticizer Carrier	A modification of our standard T-52, giving improved heat stability; and because of its cost advantage, is recommended for premium grade garden hose, tubing, clear film and sheets where water resistance is important.
ADVASTAB T-17-M	Organo-Tin Sulfur Compound	For plasticized stock, plastisols and rigids. Gives maximum heat stability necessary for prolonged cycles at high processing temperatures. Non-lubricating.
ADVASTAB T-671	Organo-Tin Sulfur Compound	For plasticized stock, plastisols and rigids. Outstanding clarity, improved odor characteristics, provides lubrication.
ADVASTAB T-50-LT	Concentrated Organo-Tin Compound	Most effective organo-tin stabilizer with lowest toxicity of any tin stabilizer known at present. Gives high clarity to plasticized and rigid vinyls.
ADVASTAB T-72	Concentrated Organo-Tin Compound	Similar to T-50-LT with improved lubricating property. For rigids and plastisols, may be used alone or with small amounts of Advastab C-79 and E-82.

OVER 100 YEARS OF EXPERIENCE

Are your troubles caused by poor dispersions?

ORDINARY DISPERSION
MAGNIFICATION 140X

If you are making your own dispersions you may be discovering some problems . . . agglomeration, costly clean-up time, excessive compounding time and contamination. ADP Dispersions will eliminate agglomeration and contamination, reduce compounding time and clean-up time in your plant. Dispersion is a highly technical science, requiring specialized research and production techniques. ADP is unique in this respect, because of its background of close to a half-century of experience. ADP specialists, without obligation, will gladly consult with you. **Their business** is dispersions, and they know it thoroughly. They will be glad to help you.

THE KEY TO HARCHEM® BETTER PLASTICS

HARFLEX® PLASTICIZERS

FOR VINYL RESINS, SYNTHETIC RUBBERS, CELLULOSE ESTERS

Outstanding for low temperature flexibility, low viscosity, low heat loss, and maintenance of flexibility over wide temperature ranges.

The Harchem Division offers you a wide choice of Plasticizers which keep your product young. Sebacate esters are particularly good on weathering and ageing.

Harchem has developed many plasticizers with special merits which enable you to select the product best suited to your needs.

Consult us if you have a plasticizer problem. Our technical staff will be glad to assist you in solving it.

Plasticizer	Boiling Point Degrees C.	Specific Gravity 20°/20°C	Viscosity Centistokes 100°F.	Major Use	Outstanding Characteristics
Dibenzyl Sebacate	265°C @ 4mm	1.055*	13.0	Vinyl Resins, Rubbers	Low Temp. Flexibility, Low Volatility
Dibutyl Sebacate	180°C @ 3mm	0.936	6.1	Vinyls, Rubbers, Cellulose Esters	Low Temp. Flexibility, Excellent Aging Qualities
Dicapryl Sebacate	230-240°C @ 4mm	0.907	13.0	Vinyl Resins	Low Temp. Flexibility, Low Volatility
Dihexyl Sebacate	184°C @ 1mm	0.911	9.2	Vinyl Resins, Rubbers	Low Temp. Flexibility, Low Cost
Diisooctyl Sebacate	248-255°C @ 4mm	0.917	15.5	Vinyl Resins	Low Temp. Flexibility, Low Volatility
Dimethyl Sebacate	294°C @ 760mm	0.986*	3.6	Cellulose Esters, Rubbers	High Solvency, Wide Compatibility
Dioctyl Sebacate	248°C @ 4mm	0.916	12.7	Vinyl Resins	Low Temp. Flexibility, Low Volatility
Dicapryl Phthalate	222-230°C @ 4mm	0.972	28.8	Vinyl Resins, Rubbers	Highly Compatible, Low Volatility
Dihexyl Phthalate	210°C @ 5 mm	0.995	28.8	Vinyl Resins	Highly Compatible, Good Flexibility
Diisodecyl Phthalate	250-257 @ 4 mm	0.966	43	Vinyl Resins	Low volatility
Dioctyl Phthalate	225-235°C @ 4mm	0.985	29.7	Vinyl Resins, Rubbers	Highly Compatible, Good Flexibility
Isooctyldecyl Phthalate	234-253°C @ 4mm	0.975	37	Vinyl Resins, Rubbers	Improved Flexibility, Permanence
Dicapryl Adipate	211-217°C @ 4mm	0.915	8.3	Vinyl Resins, Rubbers	Low Temp. Flexibility, Low Cost
Dioctyl Adipate	213°C @ 4mm	0.927	8.2	Vinyl Resins, Rubbers	Low Temp. Flexibility, Low Cost
®Harflex 300		1.098	1100	Vinyl Resins	Non-migratory, Low Temp. Flexibility
®Harflex 325		1.104	1960	Vinyl Resins	Non-migratory, Permanence
®Harflex 500	230-240°C @ 4mm	0.933	9.9	Vinyl Resins	High Heat Stability, Low Temp. Flexibility

Have You a Colorant Problem?

Poly-Supra can save you dollars in colorant costs per 100 pounds plastic without sacrifice of quality in most cases

Let's take the case of LOMA PLASTICS, INC. in Fort Worth, Texas, manufacturers of the well known LomaWare housewares line. After a telephone consultation with Mr. Louis H. Barnett, President of Loma, a trained plastics color expert flew into Fort Worth within two days, and worked in their plant for several days assisting them in setting up a dry colorant system that eliminated problems of dispersion, dusting, contamination, machine hopper feeding, etc. Research also uncovered that less dry colorants were necessary and the savings from this resulted in savings to Loma Plastics.

"THE MOLDER'S PET"

Please write us for free color chips or color matches, at no obligation, designating the exact specification of the material you would like to see in color. We will be happy to have a trained expert call on you too and work out your problems. If you wish further detailed information, call collect to Larry Krieger, Executive Vice President, HOllywood 4-7361.

We manufacture *the complete* line of dry colorants for in-plant coloring of all thermoplastic molding powders.

9055 DGP...for low cost

there is a

PLASTOLEIN® PLASTICIZER

which fits your specific needs

If you need low temperature performance...
Plastolein 9058 DOZ (di-2-ethylhexyl azelate) and 9057 DIOZ (di-iso-octyl azelate), the most versatile *low-temperature* vinyl plasticizers available, are characterized by outstanding low-temperature flex; low volatility, high plasticizing efficiency, good heat and light stability and unusually low water and soapy water extraction.

If you need extreme permanence...
Plastolein 9720 imparts extreme *durability* and *weatherability* to plastic materials—providing unusually low volatility, high resistance to oil and water extraction, excellent stability to heat and light, resistance to migration.

If you need low-cost...
Plastolein 9055 DGP is a low cost, *low-temperature, secondary* plasticizer which provides high efficiency, good all-around performance and excellent chemical stability.

Investigate the advantages of the Plastolein Plasticizer that best fit your purposes. Write Dept. FE today for *new* descriptive booklet or evaluation samples.

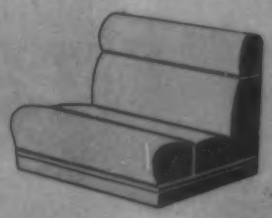
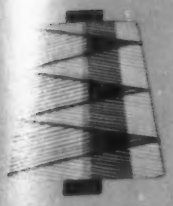
INDUSTRIAL CHEMICALS DIVISION
PITTSBURGH COKE & CHEMICAL CO.
PITTSBURGH 19, PA.



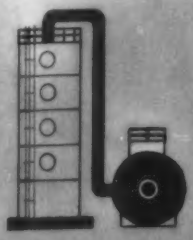
Make PITTSBURGH COKE your "One-Stop" source for Quality-Controlled INDUSTRIAL CHEMICALS!



The Industrial Chemicals Division of Pittsburgh Coke & Chemical Company offers you one of the nation's most complete families of coal-derived industrial chemicals and plasticizers.

Now, as always, you enjoy the confidence of doing business with a *basic* producer when you order from Pittsburgh. And Pittsburgh's broad selection of chemicals also offers you these other advantages:

1. A single order for more than one Pittsburgh product simplifies your paper work.
2. By ordering split carload lots of Pittsburgh Industrial Chemicals, you'll enjoy favorable carload prices on *all* of the material you order. Plasticizers can be ordered in split tank cars or tank trucks.
3. The complete facilities of Pittsburgh's Technical Service Department are ready to help you in the application of *any* Pittsburgh product.



The following listing indicates just a few typical applications for Pittsburgh Industrial Chemicals. Make it *your* check sheet for the reliable, high purity industrial chemicals and plasticizers you need!

INDUSTRY	PRODUCT	TYPICAL USES
 PAINT	Phthalic Anhydride	Manufacture of alkyd resins.
	Toluol	Solvent for lacquers, varnishes and synthetic enamels.
	Maleic Anhydride	Used in the manufacture of alkyd resins.
	Xylol	Used as a solvent in lacquers, varnishes and synthetic enamels, and the manufacture of phthalic anhydride.
	Butyl Oleate	Used in the manufacture of resinous paints.
	Phthalocyanines	Used as a pigment in high finish enamels.
	Fumaric Acid	Manufacture of alkyd resins.
	Decyl Butyl Phthalate	Anti-skinning agent in paint production.
 PLASTICS	Plasticizers	Impart plasticity to polyvinyl chloride and polyvinyl acetate resins.
	Phthalic Anhydride	Manufacture of plasticizers and polyester resins.
	Phenol	In making phenol formaldehyde resins for molding, and in making adhesives and laminating material.
	Ortho Cresol	Reaction agent in the making of synthetic resins.
	Meta Para Cresol	Production of TCP and phenolic-type resins.
	Maleic Anhydride	Manufacture of plasticizers and polyester resins.
	Benzene	Used in the manufacture of phenol and polystyrene.
	Phthalocyanines	A pigment in plastics production.
	Xylenol	A catalyst and reactant in resin manufacturing.
 PHARMA-CEUTICAL	Phthalic Anhydride	Used in the manufacture of phenol phthalein and in cortizone manufacturing.
	Phenol	Disinfectants, germicidal soaps and in the production of salicylic acid.
	Toluene	Production of sulfa drugs, benzoic acids, saccharin and other organic chemicals.
	Pyridine	Used in making penicillin, hormones, vitamins, sulfa drugs and other antibiotics.
	Alpha Picoline	Manufacture of vitamins, anesthetics and germicides.
	Beta Gamma Picoline	In production of nicotinic acid, amide and other drugs.

TEXTILE

Phthalic Anhydride	Textile specialty resins and as dye intermediates.
Maleic Anhydride	Used in the manufacture of dyes and wetting agents.
Benzene	In production of synthetic fibers and dye preparation.
Toluene	Used as a dye intermediate.
Xylene	As a dye intermediate and in synthetic fiber manufacturing.
Pyridine	In waterproofing compounds.
Alpha Picoline	In textile finishing and as a dye intermediate.
Beta Gamma Picoline	In making waterproofing compounds.
Sulfuric Acid	Used in textile finishing.
Ammonium Sulfate	As a fireproofing agent.
Phthalocyanines	In making dyestuffs and as a pigment.

INDUSTRY	PRODUCT	TYPICAL USES
 PROCESSING	**Pyridine**	Used as a solvent, HCL acceptor, and rust inhibitor.
	Sulfuric Acid, **Oleum**	As a processing agent in general industrial applications.
	Phenol, **Maleic Anhydride**, **Benzene**, **Toluene**, **Xylene**	Used as starting chemical for many organic synthetic reactions.

PITTSBURGH INDUSTRIAL CHEMICALS Commercial Data

PHTHALIC ANHYDRIDE
Shipped in 80 lb. bagged flakes and molten in tank cars (100,000 lbs.) and tank trucks (40,000 lbs.).

MALEIC ANHYDRIDE
Shipped in Leverpak drums (250 lbs. net weight).

FUMARIC ACID
Shipped in Leverpak drums (250 lbs. net weight).

PHENOL
99°, 95%, 88-91%, 80-82%. Shipped in drums (approximately 470 lbs. net), tank trucks (4,000 gals.), and tank cars (4,000, 8,000, 10,000 gals.).

ORTHO CRESOL
30° M.P., 31-24C M.P. Shipped in tank cars (4,000, 8,000, 10,000 gals.), tank trucks (4,000 gals.), and drums (approximately 470 lbs. net).

META PARA CRESOL
3° and 12°. Shipped in tank cars (4,000, 8,000, 10,000 gals.), tank trucks (4,000 gals.), and drums (approximately 470 lbs. net).

XYLENOL
3° and 12°. Shipped in tank cars (4,000, 8,000, 10,000 gals.), tank trucks (4,000 gals.), and drums (approximately 470 lbs. net).

BENZENE
Nitration 1°. Shipped in barges (250,000-300,000 gals.), tank cars (8,000, 10,000 gals.), and tank trucks (4,000 gals.).

TOLUENE
Nitration 1°. Shipped in tank cars (6,000, 8,000, 10,000 gals.), and tank trucks (4,000 gals.).

XYLENE
5°and 9°. Shipped in tank cars (6,000, 8,000, 10,000 gals.), and tank trucks (4,000 gals.).

PYRIDINE
2°, 10°, 15°, 20°, 2° shipped in tank cars (35,000 lbs.). Other grades shipped in drums (approx. 450 lbs. net).

ALPHA PICOLINE
Shipped in drums (approximately 450 lbs. net).

BETA GAMMA PICOLINE
Shipped in drums (approximately 450 lbs. net).

SULFURIC ACID
66° Be. Shipped in tank cars (50 tons), tank trucks (18 ton minimum) and barges (750 tons).

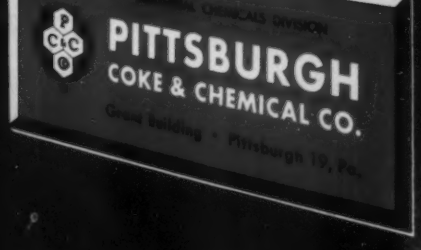
OLEUM
Shipped in tank cars (50 tons), and tank trucks (20 tons).

AMMONIUM SULFATE
Shipped unitized, bulk (20 ton min.), and in bags (100 lbs. net).

PHTHALOCYANINES
Dry powder shipped in 55 gal. drums (approximately 100 lbs. net); pressed cake and dispersed paste shipped in 55 gal. drums (approximately 400 lbs. net).

PX PLASTICIZERS
See back cover for full information.

PITTSBURGH PX PLASTICIZERS



PRODUCT	USES	AVAILABILITY
PX-108 Dilso Octyl Phthalate PX-138 DiOctyl Phthalate	Widely used basic "building type" plasticizers that exhibit an excellent combination of good standard properties.	All Pittsburgh PX Plasticizers are available in 55 gallon drums and in Tank Truck or Tank Car Loads
PX-114 Decyl Butyl Phthalate	A low cost phthalate plasticizer having good standard properties. Ideal for sheeting, tubing, wetting, and general extrusion work.	
PX-118 IsoOctyl Decyl Phthalate PX-120 Dilso Decyl Phthalate PX-800 Epoxy	Economical vinyl plasticizers. Suggested for use where low volatility and a higher degree of permanence is required.	
PX-313 Modified Alkyl Phthalate	Ideal for use in high quality calendering, sheeting, film, plastisols; and because of its low volatility, low temperature flexibility and excellent heat stability, it is equally suitable for wire jacketing.	
PX-208 Dilso Octyl Adipate PX-220 Dilso Decyl Adipate PX-238 DiOctyl Adipate PX-404 DiButyl Sebacate PX-438 DiOctyl Sebacate	For formulations requiring low temperature flexibility, heat and light stability, low volatility and low initial viscosity. Used in vinyl film compounds, polyvinylbutyral and synthetic rubber compounds.	
PX-104 DiButyl Phthalate PX-917 TriCresyl Phosphate	Used in the manufacture of polyvinyl acetate and in nitrocellulose lacquers, synthetic rubber compounds and cellulose ester-type molding compounds.

Modern Plastics' Annual Editorial Index

(Index to Volume 34, September 1956 through August 1957)

You will find this extensively cross-referenced, sixteen-page Index a welcome time saver in locating editorial material that has appeared in a full year's back issues of the magazine. More than that, you'll discover that the Index increases the value of your file copies by providing a considerably more detailed breakdown of their contents—particularly of "buried" references within an article—than is given on the "Contents" page of individual issues.

The Cumulative Index is actually three indexes in one: a General Index of Titles, an Index of Individual Subjects and an Index of Authors.

The General Index of Titles is further subdivided into separate indexes of engineering and technical articles, and the Index of Individual Subjects alphabetically cross-tabs plastics product applications in two ways: by material of composition and by product name.

To get your copy, just fill out and mail the coupon

Make

MODERN PLASTICS

articles do double duty!

Reprints of articles and features that appear in MODERN PLASTICS are often surprisingly inexpensive when ordered in quantity. Many companies make it a practice to have stories which have a bearing on their business reprinted for distribution to their own personnel, customers, prospects, stockholders, or to other interested groups.

Whenever you see editorial matter of this type in MODERN PLASTICS magazine or the Encyclopedia Issue which you can use in reprint form, in quantities of 100 copies or more, write and quotations will be furnished promptly.

Thermolite HEAT AND LIGHT STABILIZERS

ORGANOTIN

THERMOLITE 12

For all applications requiring moderate heat stability with good light stability. Excellent clarity in all vinyl resins. Has lubricating properties.

THERMOLITE 13

Powerful heat stabilizer. As an organotin maleate has dienophilic properties and thus prevents yellowing during processing of vinyl compounds at high temperatures.

THERMOLITE 17

A complex organotin stabilizer that imparts outstanding light stability to all vinyls. Heat stability is excellent and gives crystal clear vinyls. Excellent for plastisols and organosols.

THERMOLITE 20

A sulfur-containing organotin stabilizer for rigid vinyls. Has excellent lubricating properties with good heat stability.

THERMOLITE 25

All purpose organotin stabilizer for outstanding heat and light stability. Gives optical clarity in all vinyl resins. For rigids, flexibles and plastisols.

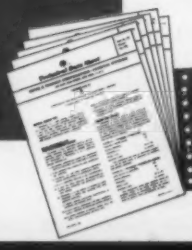
THERMOLITE 31

Most powerful stabilizer known. Unexcelled for rigid vinyls, clear or pigmented.

THERMOLITE 45

Low cost organotin stabilizer with excellent heat and light stability. No water pick-up in clear vinyl hose. For processing copolymer rigids.

BARIUM-CADMIUM



THERMOLITE 112

An entirely new concept in barium-cadmium stabilization. A liquid stabilizer containing no fatty acids or octoates. Outstanding for clear sheeting with no exudation from film — no "plate out" on calender.

LIQUID ZINC

THERMOLITE 166

A liquid zinc stabilizer to prevent sulfide staining. Used with THERMOLITE 112 to give low cost stabilization in all types of vinyl compounds.

Film and Sheeting

Today, virtually all thermoplastics are being used in varying amounts in the films (under 10 mils thick) and sheeting (over 10 mils thick) industry—and the volume continues to grow. As a guide to the many materials available, the following reports have been prepared by the various materials suppliers. For more specific details on the physical properties of the various types of plastics films, consult the Films Chart, p. 559.

SURVEY OF FILM AND SHEETING

The following materials will be covered in this section: vinyls, polyvinyl alcohol, polyvinylidene copolymer, styrene alloys, oriented styrene, polyethylene, the cellulosics, acrylics, polyester, and cellophane.

Vinyls

Because of the diversity of forms in which vinyl film and sheeting are available, this family is generally considered to include plasticized vinyl film and sheeting and unplasticized or rigid film and sheeting. In such instances, the term "vinyl" covers both polymers and copolymers, including polyvinyl chloride and polyvinyl chloride-acetate copolymers. Most of these materials are made by the calendering process. Cast vinyl film, however, in thicknesses ranging from 0.001 to 0.003 in. is also available.[1] The film is designed for use in applications where clarity, chemical inertness, and resistance to moisture vapor and common gases are required. It is finding increasing use in "skin-packaging" applications. The material is not recommended, however, for applications requiring low-temperature impact strength.

A new vinyl film to make a recent appearance has been "hard PVC film"[2]—a completely unplasticized, straight polyvinyl chloride of high molecular weight and with a specific gravity of 1.38. The film is produced on special calenders with highly polished cylinders. Special finishes such as matte or graining are made in subsequent operations. Film is stabilized by a thermal after-treatment.

Hard PVC film has good dimensional stability, wide range of heat stability, no water permeability, low WVTR, wide range of chemical resistance, strong abrasion resistance, and practically no gas permeability. All grades of the material are printable and may be die stamped without any blocking. Unoriented grades of the material may be heat-sealed, vacuum or drape formed, and die or pressure formed. Adhesives and inks used with the film are usual solvent-type vinyl dispersions. The films are recommended for use as tape bases or adhesive releases and in packaging, surfacing, light diffusers, greeting cards, and electrical and chemical insulation.

Plasticized vinyl film[3]

Methods of manufacture: Calendering. In this operation the plastic base material is premixed with suitable stabilizing and plasticizing materials. This premix is then fused in a jacketed Banbury, brought to uniform temperature on a 2-roll mill, and introduced into a 4-roll calender, where it is reduced to the desired gage.

Chemistry: The vinyl chloride plastic base material is made by polymerizing vinyl chloride monomer in suspension or emulsion systems. Ester plasticizers, such as DOP, are normally used to soften the base resin to obtain desired flexibility.

General properties: Moderate tensile strength, high elongation, good tear strength, low water absorption, moderately good chemical resistance.

Processing: Sewn, heat-sealed, or electronically sealed. Special films can be coated with pressure-sensitive adhesives.

Applications: General house-

[3] Prepared by Firestone Plastics Co., Pottstown, Pa.

ware items; raincoats; shower curtains; closet accessories; furniture covers; lampshades; venetian blind tapes; inflatable items; novelty wallets; pressure-sensitive film applications; shampoo capes; baby pants; mattress and pillow protectors; appliance and equipment covers; braided rugs.

Colors available and methods of finishing: Unlimited range in transparent, translucent, and opaque colors. Can be printed and embossed.

Plasticized vinyl chloride sheet[2]

Methods of manufacture: Same as above for vinyl film.

Chemistry and general properties: Same as above for plasticized vinyl chloride film.

Processing: Can be laminated, heat sealed, or electronically sealed. Special formulations can be coated with adhesive for pressure-sensitive tapes. Special formulations can be formed easily with good shape retention by conventional forming techniques.

Applications: Luggage covering; automotive fabrics; upholstery; flooring; inflatables; pool liners; crash panels (special formulation); pressure-sensitive tapes; novelties; handbags, shoes.

Colors available and methods of finishing: Limited color range in transparent, translucent, and opaque colors. Can be printed and embossed during or after calendering.

Rigid polyvinyl chloride film and sheeting[3]

Methods of manufacture: Calendering. Plastic base material is premixed with suitable stabilizers before being fused in a jacketed Banbury.

Chemistry: The plastic base material used for this type of film is made by polymerizing vinyl chloride monomer or combina-

RECENT DEVELOPMENTS

A bacteriostat (*Corobex,* Bex Industries, Inc.), available as a clear liquid or in powder form, is creating interest among container manufacturers, toy makers, film producers, and molders of hospital and laboratory ware. Products containing the bacteriostat are actively antiseptic, self-sterilizing, and self-deodorizing. They are mildew-static, fungi-static, and mold-static. They are nonpoisonous, nontoxic, and nonallergenic.

A new vinyl chloride film (*Wataseal FD-27,* Harte & Co.) can be used with foodstuffs without trace of odor pickup. It is nontoxic and it has been accepted by the U.S. Food and Drug Administration as a packaging material for food and beverages. Foods that contain a large amount of water can be packaged in this film without drying out.

1957 Fords and Mercurys have from 15 to 20 yd. each of polyester film (*Mylar*) over vinyl, cloth, or paper for welting used as trim on door panels and around seats. Chrysler cars use clear vinyl over a core of woven polyester film (*Mylar*) to give a metallic effect.

Unsupported polyester film (*Mylar*) with a chrome finish is available (Coating Products) in 1-mil stock sheets backed with pressure-sensitive adhesive for nonmoistening applications. It is suggested for the label, decal, point-of-purchase, silk screen, display, and decorative fields. It can be used for outdoor signs and bumper strips without lamination to other materials.

A nylon jersey-backed vinyl upholstery material (*Bolta Continental,* Bolta Products Div., The General Tire & Rubber Co.) is guaranteed against tearing and ripping where approved methods of application have been followed. The material is easy to tailor, can be pulled taut without wrinkling or sagging, and has complete recovery after repeated stretching.

A new calendered rigid vinyl sheet (Bakelite Co.) may be used in direct contact with red meats, poultry, and sea food, as well as other products. Meat and poultry can be dressed and cut at the wholesale point, then shipped in sealed containers with clear tops and placed directly on store shelves. The sheet is easily and inexpensively vacuum formed and can be heat-sealed.

A sterilizable polyethylene food film (*Steripol,* Food Film, Inc.) is less permeable than conventional polyethylene to carbon dioxide, oxygen, and water. The tubing is suggested for packaging frozen foods to be cooked in the package and materials or instruments which would be sterilized in the package.

Unplasticized vinyl film (*Nicotherm,* Ferplex Chemical Co., rep. for Rheinische Gummi und Celluloid-Fabrik), in thicknesses from 1 to more than 20 mils, is colorless and highly transparent. It is continuous-calender-polished and can be obtained oriented or unoriented. The heat resistance for both is about 175° F. The material is suggested for vacuum forming, food wrapping, industrial tapes, and sound recording.

Polyethylene film made from a new high-pressure-processed polyethylene (*Poly-Eth Hi-D 2504,* Spencer Chemical Co.) can withstand temperatures of 240° F. and is two and one-half times stiffer than conventional polyethylene. The resin is about 0.938 density and has good slip characteristics and no blocking. It is less permeable to gases and water vapor and at least three times more greaseproof than conventional polyethylene. It is suggested for use in boilable bags and in various types of overwrap packaging.

A new series of linear polyethylene calendered films (Plastic Film Sales Dept., Kendall Co.) is available in gages ranging from 0.004 to 0.025 in. and widths up to 32 inches. The same manufacturer produces blends of 75, 50, and 25% linear polyethylene with regular polyethylene. Applications will include wire and cable insulation, boilable food packaging, vacuum forming, and packaging where additional thermal properties are necessary.

tions of vinyl chloride monomer with other monomers such as vinyl acetate.

General properties: Good dimensional stability, high tensile strength, low elongation, low water absorption, good to excellent chemical resistance, self-extinguishing. Special formulations available for high light transmission.

Processing: Can be formed by vacuum, plug, ring, or other forming techniques. May be sealed with adhesives to other plastics materials and to itself. Can be coated with pressure-sensitive adhesive.

Applications: Wall covering material; luminous ceilings; louvered doors; packaging; relief maps; lithography; toys; novelties; place mats; waste baskets; shower doors; specialty laminates; wall paneling; Christmas decorations; signs; luminous letters; lampshades; and medical packaging.

Colors available and methods of finish: Almost unlimited range of translucent and opaque colors. Limited range of transparent colors. May be printed and embossed either during or after calendering.

Polyvinyl alcohol film[4]

Methods of manufacture: Band casting. The plastic base material with its modifiers is dissolved in water. This solution, controlled for viscosity and temperature, is then deposited as a wet film on a large moving belt and dried.

Types: There are two types of PVA film; namely, standard and cold water soluble. The standard type is made from the higher-molecular-weight type resins and is generally plasticized with glycerine. The cold water soluble type film is made from internally plasticized resins or low-molecular-weight resins.

Chemistry: PVA film is made from resins which have been hydrolyzed—polyvinyl acetate in the presence of methyl alcohol. There are numerous grades from high viscosity to low viscosity. PVA resin may also be internally plasticized by ethoxylation.

General properties: PVA film is impervious to oils, fats, and waxes and has a zero transmission rate for oxygen, hydrogen, helium, and nitrogen. The water permeability is necessarily rapid, because of the film's being made in water. PVA film has tensile strength which averages about 10,000 p.s.i. before stretching but has shown tensile strengths of more than 50,000 p.s.i. after stretching to 5 times the original length. The elongation of unstretched PVA film may vary from less than 10% to more than 600%, depending upon the plasticizer content and humidity. PVA films have excellent sunlight stability and have stood up in a Fadeometer for over 1,000 hours. The refractive index ranges from 1.49 to 1.53. The aging qualities are excellent with no yellowing. Color is slightly yellow to colorless.

Processing: PVA film readily heat-seals and may be laminated to other films, papers, etc.

Applications: The standard film is used as a relief agent in the molding of polyester resins and vacuum bag molding. The cold water soluble film is used as a water soluble packaging film and barrier coating.

Finishes: Can be made with a satin finish on one side of the PVA film and a glossy finish on the other side.

Polyvinylidene copolymer film[5]

Methods of manufacture: Extruded. Heat extrusion, supercooled, oriented, and blown to gage.

Chemistry: Made from ethylene (petroleum) and chlorine (brine) plus lime plus polymerization with vinyl chloride in presence of a catalyst.

General properties: Excellent chemical resistance. Permeability to water and gases lowest of all commercial films.

Processing: Heat shrinkable; can be laminated with adhesives; will heat-seal (best results obtained if sealed by high-frequency methods).

Applications: Packaging of candies, processed meats, cheeses, baked goods, nuts; also used for cap liners.

Colors available and methods of finishing: Available in a wide range of clear transparent and opaque colors.

Modified styrene/butadiene sheet[6]

Methods of manufacture: Calendering, lamination, and extrusion. The production of modified styrene-butadiene base sheets is accomplished by Banbury or mill mixing and calendering or extrusion.

Chemistry: Series, block, and graft polymerization methods are employed.

General properties: Excellent forming characteristics, good processing, fair impact strength, limited hardness and rigidity.

Processing: Can be formed, sawed, drilled, cemented and polished on standard tools and machinery. Sections can be easily cemented to each other by the following methods: 1) straight solvent and 2) solution cements.

Applications: Refrigerator and freezer liners, housewares, air conditioner housings, battery cases, toys, miscellaneous containers, display items, etc.

Colors available and methods of finishing: Colors: opaque to unlimited (not transparent). Finishes: embossing, gold leaf stamping, printing.

Rubber/resin blends[6]

Methods of manufacture: Calendering, laminating, and extrusion. In the production of styrene alloys, latex blending and/or Banbury mixing are used. Latex blending involves the blending of the copolymer latices. In the alternate method the resin and rubber phases are masticated in a Banbury mixer, extruder, or on mill rolls. Sheets are prepared by calendering and laminating in multi-deck or continuous roller presses.

Chemistry: The resin portion of the blend is made by polymerizing styrene and acrylonitrile monomers. The rubber portion of the blend is made by a similar combining of the butadiene and acrylonitrile monomers.

General properties: Excellent impact strength; high heat distortion; good chemical resistance;

[4] Prepared by Mono-Sol Corp., Gary, Ind.

[5] Prepared by The Dow Chemical Co., Midland, Mich.

[6] Prepared by The General Tire and Rubber Co., Bolta Products Div., Lawrence, Mass.

moderate hardness; fair weathering qualities, and good flexural strength.

Processing: Can be formed, sawed, drilled, cemented, and polished on standard tools and machinery. Sections can be easily cemented to each other by the following methods: 1) straight solvent and 2) solution cements.

Applications: Chemical resistant ducts, automobile headliners, kick plates, crash pads, typewriter cases, refrigerator door liners, tote boxes, trays, miscellaneous housings.

Colors available and methods of finishing: Colors: opaque to unlimited (not transparent). Finishes: embossing, gold leaf stamping, printing.

Oriented styrenes[7]

Methods of manufacture: Extrusion of sheet which is stretched in two directions under accurately controlled temperature to achieve molecular orientation.

Chemistry: Produced from polystyrene or styrene acrylonitrile copolymer as furnished by raw materials suppliers.

General properties: Oriented polystyrene has a tensile strength of 7000 to 12,000 p.s.i., a flexural strength of over 10,000 p.s.i., and a compressive strength of over 25,000 p.s.i. Its % of elongation is 3 to 10. Water absorption (%/24 hr.) is 0.04 to 0.06 mils.

Oriented styrene acrylonitrile copolymer has a tensile strength of 10,000 to 15,000 p.s.i., and a flexural strength of over 15,000 p.s.i. Its % of elongation is 40 to 70. Water absorption (%/24 hr.) is 0.5 (max.).

Processing: Depending upon the application, the film can be slit, die cut, sheeted, pressure formed, and vacuum formed. Adhesives are available, but special handling may be required. It is heat-sealable with special equipment and techniques.

Applications: Oriented styrene is used for packaging, signs displays, and for laminating to high-impact styrene sheet.

Oriented styrene acrylonitrile copolymer is used for packaging, signs, displays, blow-out windows, greenhouses, and outdoor weathering applications.

[7] Prepared by Plax Corp., Hartford, Conn.

Colors available and methods of finishing: Clear transparent and translucent colors.

Polyethylene film[8]

Methods of manufacture: See "Extrusion of Polyethylene," p. 732.

Chemistry: Polyethylene is a pure paraffinic hydrocarbon resin made by polymerizing ethylene gas at high temperature and pressure in the presence of suitable catalysts.

General properties: Good tensile, tear, and impact strength with unusually good performance at low temperatures; low moisture vapor permeability, high gas permeability, low density, therefore high area yield factor; odorless, tasteless, colorless.

Processing: Fabrication by heat-sealing on commercially available equipment. Printing on specially treated types with commercial inks on commercial presses. Pressure-sensitive adhesives can be used.

Applications: Food packaging; soft goods packaging; hardware packaging; moisture barrier in building trades; concrete curing blanket; stratosphere balloons; tarpaulins and agricultural uses, e.g., silo covers, crop mulch, etc.; drum liners; and automotive seat covers.

Colors available and methods of finishing: Natural, black, white, full line of standard colors and pastels; also, embossed.

Cellulose acetate film[9]

Methods of manufacture: A) Casting: In this operation, cellulose acetate flake, plasticizers and other modifiers are dissolved in a suitable solvent; this solution is then deposited as a wet film on a large moving wheel or belt and dried under carefully controlled conditions.

B) Extrusion.

Chemistry: Cellulose acetate flake is made by esterifying alpha-cellulose, under carefully controlled conditions, with acetic acid and anhydride in the presence of a catalyst, e.g., sulfuric acid, washing, drying, and pulverizing. Cellulose acetate flake, plasticizers, and pigments or other modifiers are converted to granules for extrusion by processing on heated rolls or mixed with solvents for the casting process.

[8] Prepared by Visking Co., Div. Union Carbide Corp., Terre Haute, Ind.

[9] Prepared by Celanese Corp. of America, Newark, N. J.

General properties: Crystal clarity; wrinkle resistance; greaseproofness; water resistance; dimensional stability; high gas permeability; good electrical insulation properties; resistance to fogging; and medium water vapor transmission.

Processing: Readily formed by heat; easily fabricated; readily solvent sealed; metalizable; heat-sealable; and easily printed by rotogravure, flexographic, and silk screen printing.

Applications: Prepackaging produce; packaged bakery products; overwraps; window cartons; window envelopes; laminates; electrical insulation; rigid containers; printed signs and displays; book covers; sound recording tape; glazing materials; lamp shades; pressure-sensitive tape; gold stamping foil; protective folders and covers; metalized ribbons; sun shades and curtains; and vacuum formed parts.

Colors available and methods of finishing: Extruded material is available in crystal and in transparent, translucent, and opaque colors. Cast material is available in crystal and in surface-colored transparents. Cellulose acetate film can be finished by printing and embossing, as well as gold leaf stamping.

Cellulose acetate sheet[9]

Methods of manufacture: Extruded. Hot pressing of sheets is used to improve optical quality or to achieve special effects. Laminates, combining two or more colors, are available.

Chemistry: Same as for acetate film, above.

General properties: Same as for acetate film, above.

Processing: Readily formed by heat; readily solvent sealed; easily metalized; can be hot formed, blown, drawn, and solvent stretched; heat-sealable; easily printed; and can be cut, blanked, stamped, stitched, drilled, punched, embossed, laminated, and cemented.

Applications: Machine guards; laminates; electrical insulation; rigid containers; printed signs and

displays; welders' shields and safety lens; glazing materials, truck curtains; protective folders and covers; metalized sequins; sun shades and curtains; vacuum formed parts; book covers; eyeglass frames; and handbags.

Colors available and methods of finishing: Available in crystal, in pearls, and in transparent, translucent, and opaque colors. Can be finished by embossing, printing, and gold leaf stamping.

Cellulose triacetate film and sheet[10]

Methods of manufacture: Cast.

Chemistry: This sheet is made by esterifying alpha-cellulose with acetic acid and anhydride in the presence of a catalyst (sulfuric acid).

General properties: Good flexibility; excellent folding endurance; high heat resistance; low shrinkage; brilliant surface finish; outstanding visual clarity; and chemical stability.

Processing: Good deep-drawing characteristics; readily heat-formed or drawn but not recommended for vacuum forming; and easily high-frequency sealed or solvent sealed.

Applications: Transparent containers; protective sleeves or folders; wallet inserts; overlays; electrical insulation; index tabs; filing equipment; greeting cards.

Colors available and methods of finishing: Clear transparent; matte one side (0.003 through 0.0075 in. only). Readily embossed or hot stamped.

Butyrate film[10]

Methods of manufacture: Cast.

Chemistry: This sheet is made by esterifying alpha-cellulose with acetic anhydride and butyric anhydride in the presence of a catalyst (sulfuric acid); the cellulose ester is given a short hydrolysis to improve its solubility and compatibility.

General properties: Soft; good dimensional stability; low moisture absorption; greater stretch and toughness; long life without loss of brilliance and clarity; and chemical stability (high degree of purity).

Processing: Excellent for lamination to metal foil, paper, and scrim; easily solvent sealed; and easily printed.

Applications: Insulation for wire winding and other electrical applications and metallic yarn.

Colors available and methods of finishing: Clear transparent.

Butyrate sheet[10]

Methods of manufacture: Dry extrusion.

Chemistry: Same as for butyrate film, above.

General properties: Exceptional shock resistance; low moisture absorption; good dimensional stability; unusual ease of forming; superior outdoor weathering resistance. Contains minor surface irregularities and lacks the excellent gage uniformity of cast sheet.

Processing: Excellent for vacuum forming and post-forming; easily high-frequency sealed or solvent sealed; and readily printed, silk-screened, or embossed.

Applications: Skin and blister packaging; advertising displays; outdoor signs; underwater diving equipment; industrial face shields; safety goggles; instrument and radio crystals.

Colors available and methods of finishing: Clear transparent; matte one side; matte two sides; press polished; and transparent and translucent colors on special order. Readily embossed or hot stamped.

Acrylics[11]

There are two types of acrylic sheet available: extruded and cast. Extruded sheet is produced from acrylic solid polymers by a melt process through suitable

[2] Source: Rohm and Haas Co., Bulletin 229d, "Physical Properties of Plexiglas."

dic Cast sheet is produced from acrylic liquid monomers by a polymerization process in suitable molds.

The significant differences between cast and extruded acrylic sheet are in strength and resistance to heat. (See Table I, p. 438). Differences in optical properties are slight. Chemical, dielectric, and weathering properties appear to be the same.

Cast sheet is usually recommended where the application requires the maximum in surface finish, clarity, toughness, and heat resistance. Extruded has been manufactured in recent years with much higher quality finish than was formerly the case, and is now acceptable for a wider range of quality finish applications.

In general, fabricating methods and procedures are the same for both cast and extruded materials, except for the following: Forming temperatures for cast sheet run about 35 to 60° higher than for extruded. Recommended oven temperatures for extruded are 260 to 305° F. and for cast, 290 to 340° F. It is not safe to heat extruded above 325° F., or cast above 360° F.

At forming temperatures, extruded sheets are softer than cast and require a greater number of clamps for support. They also have a greater tendency to stick together if touched or folded.

Cementing of extruded materials usually requires a less active or milder cement than for cast acrylics. The soak method of cementing may not be used with extruded materials. Dip and capillary methods are recommended as being more suitable.

Airplane canopies and windows, outdoor signs, and displays are representative uses of acrylics. Acrylics offer optimum clarity and good light transmission. They are strong, rigid, and resistant to sharp blows.

Polyester film[12]

Method of manufacture: Made by flat casting of the polyester polymer and subsequent treatment to produce the polyester film.

Chemistry: Polyethylene terephthalate is the condensation product resulting from the esterification reaction between ethylene glycol and terephthalic acid, or the alcoholysis of a terephthalic acid ester with ethylene glycol.

General properties: It is a clear, tough film (about ⅓ the strength of machine steel), with good elongation and impact resistance. It has very low moisture absorption, is dimensionally stable under extremes of temperature and humidity, with good retention of its physical properties. It has a low moisture vapor transmission rate, its permeability to gases is very low, and it does not embrittle at temperatures as low as −60°C. The film has a high melting point (250-255°C.) and is slow burning. It can be run on packaging machines and heat-sealed with the use of benzyl alcohol. It also has excellent resistance to acids, greases, oils, and organic solvents. Strong alkalies will affect the film, especially when hot. The polyester film has well-balanced electrical properties as measured by its good dielectric strength, high insulation, resistance, and low dissipation factor.

Processing: The film is readily printed, embossed, or delustered. It is used for metalizing and can be laminated to a wide variety of materials. Coatings add to its versatility in making bags and in various packaging applications. It can be run on packaging machines, used as an overwrap, etc.

Applications: This film is successfully used in conveyor belts, transformers, capacitors, motor insulation, insulating tape, wire coating, metallic yarn, as a gas barrier, cartography, magnetic recording tape, and general packaging. In addition, there are many unique industrial uses.

Colors available and methods of finishing: The clear film in roll or sheet form is available from the manufacturer, but processors are now making it available in many colors and special put-ups.

Cellophane[12]

General properties: A relatively tough, transparent sheet. It is hygroscopic, tougher when moist, and more friable when dry. Softeners, such as glycerol, are added to improve its durability. It is difficult to start a tear in cellophane, but once started it tears easily.

It is slow burning, but can be treated to make it nonflammable.

It is not water-vapor-proof as manufactured, but can be made so with coatings. It is grease and oil impermeable. Types that are resistant to liquid water are made.

The film will change dimensionally with changes in relative humidity.

Processing: Cellophane can be printed by all standard processes, formed into bags or overwrapped on almost any package. All types can be sealed by adhesives, and practically all coated types can be heat-sealed to themselves. Standard packaging machines can be used to process the film in the roll form, and semi-automatic machines can be used with sheets.

It can be laminated to other films, foils, and papers to obtain desirable characteristics of both materials.

Applications: The major use for cellophane is in the packaging field as bags, direct wraps, and as overwraps of trays and cartons. It is widely used as a base for pressure-sensitive tape and is used also as a parting sheet in low pressure laminations and in other special industrial applications.

Colors available and methods of finishing: Cellophane is available in a variety of colors, both plain and moistureproof. It can be obtained as sheets, rolls, or in a variety of die-cut shapes. Special types, such as non-moistureproof, semi-moistureproof, and moistureproof are available. Some varieties are heat-sealing, some can be sealed with solvents and/or adhesives. Coatings are varied to provide different characteristics for almost any end use for which cellophane is satisfactory.

RIGID SHEETS FOR THERMOFORMING

BY GEORGE S. LAAFF*

Commercially-available formable sheet materials can be classified in broad terms of basic chemical composition. Detailed information, including the producing companies and trade designations, are listed in the Plastics Properties Chart.

A summary of the range of physical, thermal, and electrical properties of the more commonly used formable rigid thermoplastic sheets is presented in Table I, p. 441.

Rigid vinyl

This material is a vinyl chloride/vinyl acetate or similar copolymer, known as "rigid vinyl."

Rigid vinyl has good physical and chemical properties as well as good forming characteristics. It lends itself especially to vacuum and blow molding. The surface of the sheet is usually suitable for printing operations. Large quantities of this material are overprinted with designs and pictures for three-dimensional store displays, ornaments, and the large field of Christmas decorations. The market for rigid vinyl formable sheet in this area is well-established.

Rigid PVC Type I[1]

This classification is also known as UPVC (unplasticized), nonplasticized, unmodified, and normal-impact sheet.

Most PVC has been fabricated using hot-gas welding techniques which are slow and expensive. Heat-forming methods have been used largely to make angular bends. As a cost-saving device, heat-forming is increasingly used.

A peculiarity of unplasticized PVC is that its maximum elongation is reached at approximately 212° F., a point at which it still has fair tensile strength, while its minimum tensile strength is at temperatures above 300° F. Consequently, it is recommended that PVC be formed at temperatures in the neighborhood of 212° F., using high pressures. Forming at higher temperatures with lower pressures may cause rupturing in the mold. Ring-and-plug molding, allowing high pressures, is preferred.

Rigid PVC Type II[1]

This material is modified with acrylonitrile rubber and is referred to also as high-impact, modified, or medium-chemical-resistant polyvinyl chloride sheet.

Rigid PVC Type II has lower chemical resistance than Type I. It was developed for applications where impact resistance is more important than chemical resistance. The heat-forming techniques for Type II are similar to those for Type I.

Styrene-acrylonitrile and butadiene-acrylonitrile

From the standpoint of sheet thermoforming, these materials have a most interesting combination of properties. With excellent physical, chemical, and forming properties, they are used for many applications where clarity or transparency is not essential. The combination of high heat-distortion temperature, high impact strength, good chemical resistance, and embossed-grain retention has resulted in a wide range of industrial applications including boxes and cases, machine housings, interior automotive trim, etc. Their compatibility with fire-retardant resins, combined with low specific gravity, makes them ideal for interior trim in aircraft.

Sheets of resin-rubber blends are formed by vacuum and positive-pressure methods such as blow molding and ring-and-plug, or combinations of all three. Ordinary woodworking tools can be used in all necessary finishing operations.

Styrene-butadiene

This extensively-used material is GR-S rubber-modified polystyrene and is known as medium- and high-impact styrene sheet, depending upon the extent of GR-S rubber modification.

Of the medium- and high-impact sheets, the former is well-known and has been available for many years as extruded sheet. Its great advantage is ease of forming by vacuum or positive-pressure methods. Perhaps its best known application is for refrigerator door liners. The recent development of a high-gloss sheet, produced by laminating an oriented polystyrene film to the surface of extruded sheets, has opened the way to new applications.

High-impact styrene sheet is a more recent introduction to the formable sheet industry. Its applications include those where lower chemical resistance can be tolerated (it is attacked by strong acids and organic solvents).

Cellulose acetate

This material is the product of the reaction of cellulose with acetic anhydride, resulting in a relatively odorless product, which can be cast or extruded into film or sheets of various formulations. Some of its principal physical properties are good toughness and rigidity, formability, and heat and

* Manager, Research and Development, Bolta Products Div., General Tire & Rubber Co., Lawrence, Mass.

[1] U. S. Dept. of Commerce C. S. 20155

solvent sealability. This material, because of its superb clarity, formability, and toughness, finds increasing usage in packaging.

Cellulose acetate butyrate

The chemical composition of this material has long been known. The butyrate radical substituted for part of the acetate improves the physical properties, principally toughness and resilience. CAB continues to find extensive usage in the manufacture of both indoor and outdoor signs. One of the grades, Formula #469, has exceptional resistance to outdoor weathering.

Polymethyl methacrylate

This material is produced by a casting process in which methyl methacrylate is polymerized in step presses. It has a long and distinguished past under tradenames of Lucite and Plexiglas. Du Pont has ceased manufacture of Lucite sheets but still sells materials for casting.

The combination of good physical and optical properties, resistance to weathering, dimensional stability, and ease of heat-forming has been responsible for its extensive use in aircraft for glazing cockpit canopies and also as outdoor display signs. The polymer also conducts light. Although this material has low impact strength, it shatters into chunks rather than shards. All conventional methods of forming and post-fabrication apply.

Polyethylene

Polyethylene sheet in thin gages is widely used as a packaging material because it is an excellent moisture vapor barrier, has good chemical resistance, and has excellent low-temperature flexibility and impact resistance.

Disadvantages of polyethylene are low oxidation resistance which limits its use outdoors, low heat-distortion temperature, and high creep.

Linear polyethylene has been experimentally extruded in sheet form but such sheets are not commercially available today because of unavailability of the polymer. This is one of the materials that offers considerable promise to the vacuum forming industry. The combination of chemical inertness and high heat resistance should fill the need where the presently-available sheet materials have not been satisfactory.

A creditable list of materials, offering a wide range of properties and processes, is available to sheet formers and fabricators today. The fabricator must analyze the requirements and gain complete knowledge of the properties and the optimum fabrication methods for each material.

[1] Not commercially available in sheet form.
[2] Special techniques required.

Laminated Materials

While plastics films offer a diverse range of properties, there is, of course, no single all-purpose material yet available that will answer all requirements. Industry has found, however, that the closest approach yet made to an all-purpose material is available in the concept of laminating two or more films—each with specific desired properties—together. Moreover, by adding other than plastics films, e.g., aluminum foil, paper, cloth, etc., still a wider range of properties and characteristics is possible.

In many instances, even a combination of two materials is not sufficient to meet specialized performance requirements. A third or fourth component is, therefore, added to the laminated structure, e.g., four-web combination of cloth, polyethylene film, Kraft paper, and vinyl film to make the standard type of water-vapor barrier specified by the military.

Types of laminates

The description of a laminated structure is generally applied to a combination of two or more webs joined together by the use of an adhesive layer between the webs. In contrast, a coating would be defined as a substance deposited while in the liquid state on a web without the use of adhesive means. The popular new technique of extrusion-coating seems to fall in the latter category and is generally not considered as a process for making a laminate.

Processing and fabrication[1]

Using the techniques described below, almost all flexible plastics films can be put to use in laminates. The list already includes polyester film, polyethylene, vinyl, saran, acetate, Pliofilm, and there is even talk of nylon. Among the nonplastics materials, the most popular in use in laminations is paper, followed by aluminum foil and fabric cloth.

The desired end properties and requirements govern the selection of materials to be combined and, to an extent, the adhesives and combining techniques employed. Most laminations are made by one of the following methods:

Wet laminations: Adhesives are usually aqueous solutions or dispersions, but solvent cements can also be used. In this method, the adhesive is applied by a suitable applicator roll, the two webs joined under pressure from nip rolls and the solvent evaporated. Laminations of this type require that one of the materials be porous to permit escape of solvent or water vapor.

Thermoplastic: This method is particularly adaptable to laminating nonporous materials. A thermoplastic base adhesive is applied to one web, the solvent is removed by heat, and the second web is joined by pressure from a heated roll. The laminate is then passed over cooling rolls prior to being wound in rolls.

Hot melts: This is one of the simplest types of laminations. No drying chamber is required since there is no solvent to evaporate. The adhesive is applied hot to one web and the other brought in contact while the adhesive is still molten. The laminate is then cooled and wound into roll form.

Contact: Pressure-sensitive or contact adhesives are used by a method similar to the thermoplastic technique. The chief difference is that heat is not required to activate the adhesive. Instead, pressure from nip rolls serves to produce the bond.

Calendering and extruding: Films may be calendered or extruded on flexible webs such as paper, aluminum foil, and other films. While this is not in the strictest sense a laminating procedure, the effect is the same since a multiple web results. The limitations of this process are the types of materials that can be calendered or extruded and the kind of supporting webs that will fit the application requirements.

The selection of the proper adhesive, of course, can have an important effect on the success of the end-use application. A good example is the recent development of the "heat-and-eat" type of package which is fabricated of a polyethylene-to-polyester film lamination. Because of the rigorous requirements of the application, it was necessary to select an adhesive that could take boiling temperatures (when the bag is placed in boiling water during the cooking phase) or sub-zero temperatures (during storage in a freezer) without delaminating.

Applications

The availability of laminates offering a wide range of properties has already started to open up a number of new applications. The "heat-and-eat" application described above (and based on a polyethylene-polyester lamination) is regarded as one of the most important new trends in the packaging industry. Similarly, polyethylene-to-cellophane laminations (polyethylene adds strength and liquid-holding qualities) are responsible for most of the unit- and pouch-packaging of liquid and viscous products.

One of the most exciting developments in recent years has been the application of vacuum protection in a flexible package—and again, the problems connected with this type of packaging could not have been solved without laminated structures. Single films either lacked gas impermeability or could not be used on the special equipment adapted for vacuumizing and sealing.

Materials

Each plastic film has its own special properties to offer to the final laminate, making it possible to engineer a material that can "breathe," hold gases, withstand boiling water, hold fats and oils, be heat-sealable, etc.

Polyethylene, for example, is usually used to impart waterproofness or heat sealability to the substrate and can be combined with such materials as paper, cellophane, polyester film, aluminum foil, fabrics, etc., for use in vacuum packaging meats, for "heat-and-eat" packages, multi-wall bags, sugar pouches,

[1] Prepared by W. P. Andrews, Reynolds Metals Co., 3840 Georgia St., Gary, Ind.

and many similar applications. The polyethylene-cellophane combination has proved especially effective (and is probably the largest volumewise of all the laminates). Cellophane, on the one hand, is a good gas barrier when dry, but has low flex and tear resistance. Polyethylene, on the other hand, is more permeable to gases, but has good flex and tear resistance. Therefore, these materials naturally complement one another and make a good material for vacuum packaging luncheon meats and cheeses, among others.

Pliofilm's positive heat-seal quality, coupled with its flexing properties, makes it a very suitable film for laminations. Pliofilm can be laminated to any of the packaging films, foil, paper, or board stock. Either lacquer-type or water-dispersed adhesives are used to effect strong bonds with satisfactory aging qualities. Acetate-to-Pliofilm, for example, is a lamination that is a good moisture barrier, is durable, grease-resistant, and can be heat-sealed. The combination is especially useful in the packaging of pharmaceuticals.

Even nylon film is showing potential as a possible material for laminate structures. While the film is markedly permeable to water vapors, it has low oxygen permeability, is very tough, and is resistant to hydrocarbons.

Acetate laminations

As an indication of the versatility which the laminates can offer, acetate film can be singled out as an example.

Types of laminates available: Acetate laminated to any one of the following: paper, printed paper and boards, aluminum foil, tissue, fabric, cotton scrim, metal screening, aluminum foil, Pliofilm, polyethylene, saran, or vinyl.

Forms available: Rolls and cut-to-size sheets.

Method of laminating: In the continuous laminating process, the emulsion, lacquer, or hot-melt adhesive is applied to the acetate film and the combination is achieved between heated pressure rolls.

Gage of laminating film: For most applications, the thickness of the acetate film is in the range of 0.00088 to 0.002 inch. On some applications, thicker material up to 0.010 in. is used.

General properties: Good surface appearance, clarity, and depth; increased fold resistance; water resistance; good electrical qualities; and fogging resistance.

By combining with other materials, the properties of the completed laminate can be controlled with regard to moisture vapor transmission, gas transmission, toughness, foldability, etc.

Typical applications: Glazing material; greaseproof barrier wraps; electrical insulations; packaging; adhesive tape base; boxes; labels; book covers; displays; menus; calendars; greeting cards; bags; envelopes; shelf covers; and ribbons.

Finishing methods: Laminates made with plastics films can be finished by embossing, printing, and gold leaf stamping.

Aluminum foil laminates[1]

The two materials that are most commonly combined with plastics films are paper and aluminum foil. Paper adds strength, support, and body to the laminate and is inexpensive. Aluminum foil in the heavier gages is a positive barrier to moisture, gases, and light, and is most effective when combined with films that offer flex and tear resistance and heat-seal properties. Therefore, laminates of the general type, aluminum foil-paper-aluminum foil-Pliofilm or polyethylene, are used for packaging such products as yeast, dehydrated soups, hygroscopic citrus fruit powders, and milk powders. These combinations offer excellent moisture protection, durability, and esthetic qualities. Yeast requires protection from oxygen, so the air in the package is replaced with nitrogen gas. For gas packaging, saran and some types of Pliofilm are more satisfactory as the heat-sealable member of the laminate than polyethylene.

A combination of paper-aluminum foil-polyethylene is used for dehydrated soup and photographic film. Aluminum foil-paper-polyethylene is an excellent material for packaging frozen foods, since it permits them to be reheated by dropping the package in boiling water. Some Mylar-polyethylene is also being used for this purpose.

For packaging headache tablets and effervescent drink tablets, where a high degree of moisture protection is needed, cellulose acetate-aluminum foil-polyethylene or vinyl copolymer laminates are used. The inner film is for heat-seal properties, while the reverse-printed acetate film decorates the package and protects the foil from physical damage which might impair the moisture protection afforded by it.

Paper-polyethylene-aluminum foil-polyethylene combinations are used for gas packaging items such as dehydrated potatoes. In this construction, foil is protected from rupture by the two layers of polyethylene, and, therefore, maintains a gas-tight package. Although it has not been widely used as yet, a laminate consisting of Mylar-aluminum foil-saran gives excellent protection to the passage of gases and should find many applications. This combination is extremely tough, is resistant to greases and chemicals, may be used over a wide range of temperatures, and can be heat-sealed to give a strong bond.

Combinations of cellulose acetate and Pliofilm, acetate and saran, and cellulose acetate and vinyl-coated aluminum foil are used for packaging many pharmaceuticals.

In addition to packaging applications, laminated film products are also used in industrial applications. Metallic yarn is made of cellulose acetate butyrate-aluminum foil-butyrate and Mylar-aluminum foil-Mylar combinations.

Mylar-aluminum foil combinations are used for insulating pipe wrap as are cloth-Mylar-aluminum foil. The foil serves as a vapor barrier and reflective insulator, while Mylar adds flex and abrasion resistance. Mylar is being laminated to vinyl films for use in wallboard and counter and table tops. Many electrical applications are being investigated for aluminum foil-Mylar combinations.

Decorating Film and Sheeting

BY GEORGE S. LAAFF*

RECENT DEVELOPMENTS

A high-gloss, water- and oil-resistant ink (*Safe-T-Brite*, Bensing Bros. & Deeney), for flexographic printing of treated polyethylene, polyester film (*Mylar*), and saran-coated cellophane, uses a nontoxic vehicle and a high flash-point solvent. It has the same degree of moisture resistance as impervious coatings, eliminating the need for overprint varnish on films that will be exposed to severe moisture conditions.

A new bonding process (Seiberling Rubber Co.) for adhering embossed polyester film (*Mylar*) to a variety of other rigid and flexible materials (including plastics, pressed wood, steel, and aluminum) is based on the use of a thermosetting adhesive, plus a special combination of time, heat, and pressure. Sheet metal can be shaped after the surfacing has been applied. Anticipated applications include coverings for radio cabinets, air conditioners, refrigerators, and other household appliances.

A stock range of vinyl fabrics (Goodall-Sanford, Inc.) is engineered and styled for the seat cover field. An unsupported vinyl (*Goodallite Coronado*) is available in 10 colors, and a cotton knit supported vinyl (*Goodallite Readington*) is offered in 14 colors.

A line of vinyl-cloth laminations (Scranton Lace Co.) consists of plain, printed, and embossed vinyl sheet laminated to drills, twills, cotton knits, sheeting, nylon backing cloths, and other fabrics. Applications include luggage, beach umbrellas, tarpaulins, and outdoor furniture, as well as baby carriages.

The most common methods used today to decorate plastics film and sheeting are embossing and printing. (See Table I, p. 445.)

A variety of effects can also be achieved by *laminating* plastics films to colored sheets or to fabric, paper, or foil. By sandwiching decorative fillers, e.g., natural or synthetic flora and fauna, fibers, fabrics, etc., between two transparent sheets in a laminate, an unlimited number of imaginative designs can be created. Certain thin transparent films, e.g., oriented styrene, can also be printed on their reverse side before being laminated to heavier plastic sheeting.

The quilting of film and sheeting (or other decorative effects) may be accomplished by high-frequency *sealing* or *stitching* two pieces of material together, using foamed plastic, paper, or natural or synthetic fiber waddings as the interlayer.

The *flocking* of colored fibers on film and sheeting offers still another way of enhancing appearance. Reportedly, in many applications, the film or sheeting can be flocked either before or after the fabrication process takes place.

Attractive effects may also be imparted to film and sheeting by the *addition of materials during compounding*, e.g., fish-scale extract for a pearl effect, or metallic powders for a lustrous sheen.

Metalized film and sheeting is another material that offers decorative possibilities. Metal effects can be obtained, for example, by laminating metalized Mylar to vinyl film and sheeting.

Ruffling and *crimping* may also be used to improve the appearance of fabricated items.

EMBOSSING PROCESSES

The art of forming surface patterns in relief by embossing a design into the material is widely used to decorate and increase the utility of both film and sheeting. Embossing is usually accomplished by one of two principal methods: plate or press embossing, or roller embossing.

Surface designs in relief may also be obtained in cast film by reproducing the surface on which the film is cast. Two methods are used: 1) evaporation of differential solvents, and 2) exposure of the film or sheeting to electronic waves to get a crinkled effect.

Plate embossing

Commonly used for producing alligator and similar deep-grained patterns in vinyl sheeting, plate embossing is performed with heated mechanical or hydraulic flat-bed presses. In this process, a metal plate engraved with the desired pattern is clamped to the upper platen of the press. The upper platen is heated either by steam or high-pressure hot water. The matrix, or female embossing plate, is fastened to the bottom platen which is not heated. The matrix is a soft, fibrous sheeting which is usually made of paper or felt formed to the necessary contour by wetting and then pressed against the embossing plate.

Most quick-acting presses are built with stationary top platen

and movable bottom platen. Sheets or continuous rolls of stock are fed mechanically or by hand into the press and positioned between the engraved plate and the matrix. The press is closed for a period of time necessary to achieve permanent embossing, which may vary from a few seconds to 1 minute. Film and sheeting subjected in this manner to mechanical pressure and heated to their flow points, take on the contours of the engraved plate. Temperature, pressure, dwell time, and the quality and depth of the engraving are all critical factors in satisfactory embossing.

In limited applications, heated plastic sheets are embossed with coarse textured cloths, wire screens, woven rattan, or similar materials. Plate embossing is generally satisfactory for short runs and embossing of small sheets.

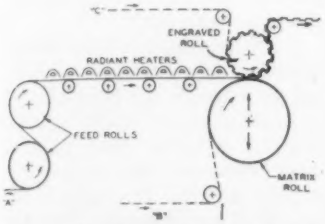

Fig. 1: Radiant preheated embossing roller laminator

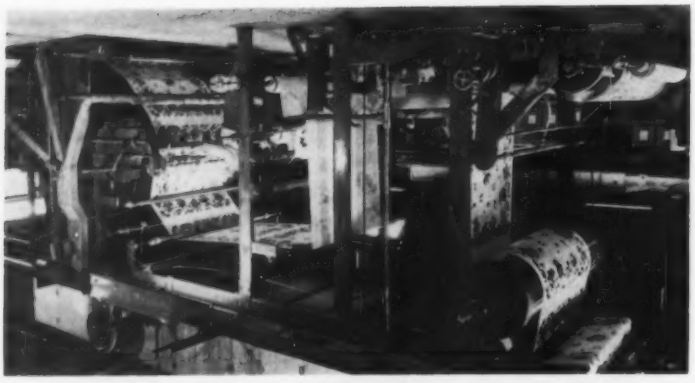
In production embossing of continuous film and plastic sheeting, the resulting plate marks or overlaps are objectionable and roller embossing is preferred.

Roller embossing



Generally used for shallow and deep grain embossing such as skiver, box calf, moire, etc., the roller embosser (Fig. 1, above) operates on the same general principles as the flat-bed press, except that the design is engraved on the surface of a steel roll instead of a flat plate. Heated plastic film or sheeting is passed between the engraved roll and a backing or matrix roll.

Formerly, matrix rolls were made of pressed paper, cotton, or wool, but almost all of the rolls in current use are rubber rolls. The density or hardness of the backing roll is dependent upon the depth of engraving in the steel embossing roll. Usually, high-density rolls are used for shallow patterns and low-density rolls for deep patterns. Paper matrix rolls are saturated with water and then brought into intimate contact with the engraved roll to "run in" or "cut in" the design of the engraving. This reproduces a counter impression of the engraving in the bed roll which contributes toward clear, well defined embossed designs.

The amount of heat and pressure applied varies considerably; it is dependent upon the nature of the material to be embossed, thickness, pattern desired, and

TABLE I: Summary of processes for decorating film and sheeting

Process	*Special purpose or advantage*	*End use*
Plate embossing continuous sheets	Deep embossings.	Alligator embossed PVC sheeting for the shoe & handbag trades.
Plate embossing sheets	For short runs and small sheets.	Place mats, tablecloths, handbag and shoe materials.
Roller embossing	For more reasonable production rates.	Upholstery and automotive materials.
Vacuum embossing	Specialty embossing, short runs, deep draws.	Novelties and automotive.
Rotogravure printing	Fine detail in printing. Many different colors. High rate of production.	Shower curtains, cottage sets, dinette material, upholstery, and automotive.
Surface printing	Imparts 3D properties, hand-painted effects.	Shower curtains, tablecloths, cottage sets.
Topping	Two-tone effect.	Handbags and shoes.
Flexographic printing	As many as 6 colors printed continuously. Low-cost engraving.	Inflatable toys.
Spanishing	Two-tone effect on embossed material.	Handbags and shoes.
Valley printing	Simulates fabrics.	Upholstery, automotive, wall covering.
Transfer printing	Multi-color design on small pieces. Excellent detail and register.	For cards and novelty items. Products where excellent registration is required.
Laminating metalized film to vinyl film and sheeting	Simulated metal finishes.	Automotive interior trim, shoes, handbags, and novelties.
Sandwiching decorative media between transparent film and sheeting	Decoration with natural or abstract figures and designs (flora and fauna, strands, fibers, fabrics).	Novelties.
Stencil printing (plastisol island printing)	Unlimited design possibilities. Moisture vapor transmission imparts seating comfort.	Automotive and furniture upholstery.

Vinyl film, printed by the gravure process in multi-color, is later embossed and slit into tablecloths. (Photo, General Tire & Rubber Co.)

speed at which the operation is performed. As a general rule, deeper patterns require greater heat and pressure. Since the plastic sheeting must be cooled to set the impression, embossing is generally accomplished by using a cold engraved roll with plastic film or sheeting that has been preheated.

Low-pressure roll embossing

There has been a decided trend toward a method commonly known as low-pressure roll embossing. In this process the plastic sheeting is heated to a temperature between 250 and 340° F. and passed between the metal embossing roll, usually of thin-walled shell construction, and a rubber roll slightly larger in diameter. The steel roll is internally cooled by brine or circulating cold water. The rubber roll is cooled by immersion in a trough of running cold water. To avoid blisters in the sheeting, excess water is removed from the surface of the rubber roll before contact is made with the vinyl film. This is accomplished by use of squeeze rolls, rubber wiper blades (squeegees), air knives, or a combination of methods.

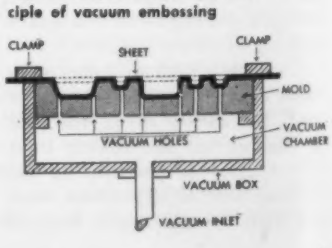
Most low-pressure installations have a heating table arrangement varying in length from 4 to 8 feet. The plastic sheeting, supported on a conveyor, passes underneath and in very close proximity to radiant heaters. Such a conveyor is essential in the handling of unsupported film. It is of utmost importance to have the heating arrangement as close as possible to the nip of the embossing rolls in order to prevent cooling of the material before embossing. After the plastic sheeting leaves the embossing rolls, it passes over one or a combination of several cooling drums.

The compactness of this type of embossing enables tandem operation with coating or calendering equipment. The plastic can be embossed directly off the calender or organosol-plastisol coating machine, since at this point the plastic material is most receptive to low-pressure embossing.

Great strides have been made in embossing *off* the calender, with the low-pressure embossing unit mounted as close as possible to the last calender roll. At a minimum distance, an optimum embossing condition exists when the vinyl film is coming off the calender at its true softening or flow point. If the embossing unit cannot be mounted sufficiently close to the calender, additional heating equipment must be provided to maintain the softening temperature. Patterns pressed into vinyl film and sheeting at high pressure but at temperatures below the true softening point of the film lack permanency and adversely affect the dimensional stability and strength of the sheeting. In high-speed production, higher mechanical pressures and temperatures are needed to achieve optimum physical properties. It is good practice to carry the film around the embossing roll as far as possible in order to increase dwell time.

Most of the difficulties encountered in embossing off the calender are caused by unsuitable rubber rolls. High operating speeds and, more especially, extremely high temperatures and plasticizer vapors rapidly deteriorate rubber rolls, causing costly production delays. Special types of rubber, varying densities, etc., have alleviated production shutdowns. In postcalender embossing, as well as other low-pressure operations, the rubber roll is usually gear driven while the steel roll is driven by contact only.

Embossing *on* the calender is the latest development in this field. In this process, the vinyl sheeting is embossed directly against the last calender roll instead of against an auxiliary rubber covered roll. This method is very limited and is extremely difficult to perform.



An increasing number of manufacturers are embossing directly *off* the calender due to advantages in cost and ease of operation. This method is highly economical in long production runs as the speed of the calender is geared to the speed of the embosser. Frequent roll changes, however, seriously impede the calender efficiency. A low-pressure embossing machine, built to accommodate the same embossing rolls used in *off* calender embossing, provides versatility without additional roll costs.

Additional fine decorative effects are achieved by inlay or ink embossing where inks are transferred from the high points of the engraving into the valleys of the embossed pattern.

Vacuum embossing

The newest technique for film or sheet embossing is vacuum embossing (Fig. 2, below). Polyethylene or vinyl films are drawn against an engraved plate or a mold provided with suction holes

Fig. 2: Diagram showing principle of vacuum embossing

or a textured fabric which is against a perforated steel plate attached to a suction device. The film, at its flow-point temperature and under atmospheric pressure, readily accepts the texture of the engraving or the fabric. This process is applied to single sheets or continuous rolls for place mats, tablecloths, handbags, etc.

PRINTING INKS

Printing inks for decorating plastics film and sheeting are composed of colorants dispersed in a resin binder. Since the surfaces of plastics film and sheeting are nonporous, the principle of printing differs from that which is ordinarily employed for paper, textiles, and other materials having absorbent surfaces.

Most inks used contain volatile solvent and a binder of the same general type resin as the film to be printed. When the ink strikes the film, the solvent partially dissolves the film surface at points of contact and, upon evaporation of the solvent, the surface dries with the pigmented binder as an integral part of the film. This process is limited to films for which solvents are commercially available. There are also aqueous dispersion inks available which do not dissolve the film but become an integral part of the film after they have been thoroughly dried.

Special surface preparations, such as the Kreidl process, are necessary for satisfactory ink adhesion to polyethylene.

The following are two typical examples of printing ink formulations for polyvinyl chloride flexible sheeting:

1) Inorganic pigment (as listed previously)	32%
Resin binder (polyvinyl chloride acetate copolymer and/or other resins	13%
Solvents (ketone type)	55%
2) Organic pigment such as phthalocyanine green or blue (as listed previously)	7%
Resin binder	10%
Solvent	83%

The pigments generally used in the vinyl inks are: White—titanium dioxide, calcium carbonate, calcium sulfate, barium sul-

MANUFACTURERS OF *Embossing Rollers and Plates*

324 ST. PAUL ST., ROCHESTER 5, NEW YORK

Do you know all the latest ways to cut your packaging costs?

Are you familiar with new developments in package design that stimulate retail sales?

Are you sure you're using the best kind of package to protect your product from damage?

If you had to answer "No" to any one of these questions, it's likely that you're unnecessarily losing money every business day.

Fortunately there's an easy way out: MODERN PACKAGING magazine! It's the world's most authoritative publication devoted exclusively to packaging problems and their solutions. It analyzes all of the newest developments in packaging—materials, machinery, design and production. It reports each of the latest ways to merchandise packaged products of all types, from frozen foods to monkey wrenches.

The cost of an annual thirteen-issue subscription—including the giant annual Encyclopedia Issue—is only $7.00 in the U.S., its possessions and Canada; $20 elsewhere. You can begin yours today simply by writing us on your business letterhead. We'll bill you later.

fate; Black—carbon black, lamp black, bone black; Red—calcium and barium salts of permanent red 2B, lithol rubine, cadmium selenide, iron oxide; Green — phthalocyanine green, light chrome green; Yellow — chrome yellow, chrome oxide; Orange—molybdate orange, iron oxide, and cadmium sulfide; and Blue—phthalocyanine blue, ultramarine blue, iron blue.

PRINTING PROCESSES

The most important method of printing film and sheeting utilizes engraved rollers since continuous, high-speed production is desired. Three types of rollers may be employed: 1) solid copper shells, which are the most economical for reproducing designs with small "repeats," 2) copper-plated steel cylinders, which are more practical for larger areas, and 3) steel rolls or cylinders.

Copper or copper-plated rollers may be engraved by three methods. The *die and mill process* is used to engrave patterns having very small or no "repeats," such as fine checks and continuous stripes. The *pantograph process* is employed to reproduce designs of variable area coverage, up to 100%, or a combination of solid and half-tones. The *gravure process*, or photoengraving, is the most important method of engraving since excellent detail in reproduction of art-work is obtained. A complete range of tones can be printed by the latter method which results in clarity of fine detail and unusual photographic effects; multi-color printing is possible by using three or more rollers.

Gravure printing

The most widely used method of printing both heavy- and light-gage vinyl film is gravure printing (Fig. 3, p. 450). It consists of depositing ink onto the surface to be printed from the recesses of a photoengraved plate or cylinder. The pattern to be printed is etched into the metal in the form of small cups. Gravure screens vary in size from 75 to 300 lines per inch.

Rigid plastic sheeting

for every purpose

Stock sizes up to 51"x 108".

Available transparent, translucent, or opaque—in a wide range of colors.

Scranton Plastic Laminating corp. 3218 PITTSTON AVE., SCRANTON 6, PA.

is delivered to the cells by contact with a furnish roll or by immersion of the lower portion of the print roll. Excess color above the level of the cells as well as on unengraved areas is removed by a sharp, thin knife-edge doctor blade pressing against the engraved cylinder surface. The "doctored" roll, containing a measured amount of ink in the engraving, is brought into contact, under pressure, with the surface of the film or sheeting to be printed and the ink is transferred from the engraving to the film.

Gravure printing machines are available for printing patterns with one to twelve colors. Variations in depth of color from a single engraving are possible through differences in depth of engraving. By limiting the quantity of ink deposited through the use of a shallow engraving, the color of the film may be allowed to show through and change the tone of the printed color.

Due to lack of absorbency of plastics films, surface drying is necessary between print cylinders. The areas printed first will, on reaching the next position on the print machine, be in contact with the smooth unengraved portion and, if the ink is not dry, smudging will result.

Typical examples of gravure printing include shower curtains, dinette sets, tablecloths, and cottage sets.

Over-printing is a form of gravure printing. In this method, a yellow pigment is printed first, then a red, and finally a blue. A multi-colored effect is obtained by varying engraving depths. The yellow, usually a chrome pigment, must be opaque in order to hide completely the color of the film on which it is printed. The red and

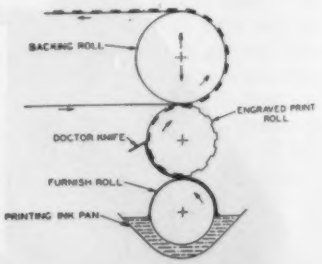

Fig. 3: Schematic drawing of gravure printing process

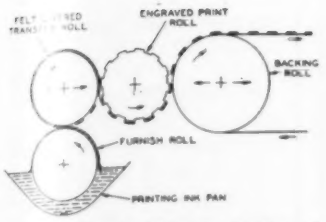

Fig. 4: Schematic drawing of surface printing process

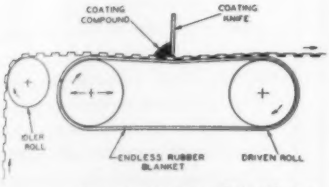

Fig. 5: Diagram of "knife-on-blanket" spanishing unit

blue, however, must be as transparent as possible in order to take full advantage of the light filtering effect.

Reverse printing is another form of gravure printing. In this process, the ink is applied to the reverse side of a transparent film. Usually, the application is on heavy-gage film used for upholstery applications where abrasion resistance is important. Multi-color patterns with a solid background are obtained by first printing the pattern, then a solid color blotch over the printed pattern. Maximum opacity is, of course, necessary for all the pigments used in this process.

Surface printing

The surface printing process (Fig. 4, above) is adopted from wallpaper printing. Three-dimensional effects may be obtained and up to 12 colors may be used. The engraved pattern is raised about 3/16 in. above the core of the roll instead of being recessed as in gravure printing. The raised engraving permits application of a large number of colors by continuous process without smudging. Drying is not required between print nips.

Color is furnished to the raised engraving by a covered transfer roll, which is color-fed by surface contact with a metal roller immersed in the ink pan. The wet layer of ink on the engraving, about 2 mils thick, is transferred to the film by "kiss" printing with a minimum of pressure. Excessive pressure produces a so-called "back-lash" which is an undesirable large ring or halo around each pattern. A *small* halo, however, is desirable since it imparts a three-dimensional as well as a hand-painted effect. This type of printing is widely employed for plastics drapes, place mats, and shower curtains.

Spanishing

This method, commonly used by the leather industry, has been adapted for use by plastics film and sheeting converters. The ink is wiped into the valleys of embossed film or sheeting by either "knife on blanket" (Fig. 5, left), or by "wipe roll" (Fig. 6, below), machines. This method of finishing was the precursor of "valley printing" described below. It is widely used for handbag, belt, and shoe applications.

Tipping or *topping* produces a two-tone decorative effect inverse to "spanishing"; i.e., the high points, instead of the valleys, of the embossed film or sheeting are inked. Neither "spanishing" nor "topping" produces very elaborately decorative finishes and these processes are slowly yielding to flexographic printing and valley printing.

Flexographic printing

Formerly known as aniline printing, flexographic printing (Fig. 7, right) is not widely practiced on vinyl film but has proved successful for the processing of specific items. Inks used in flexographic printing must not attack rubber rollers or rubber engravings. Consequently, practical considerations limit the application to alcohol and water inks. A method of printing water-soluble inks with subsequent solvent resin topcoating has proven successful. The type of engraving used in a flexographic press is similar to that used in surface printing except that the rolls are made of rubber. The raised engraving in the flexographic process makes it possible to print up to six colors continuously. Inflatable toys and other seasonal or disposable items are suited for this type of printing due to the low cost and ease of cutting or molding rubber engravings.

Valley printing

One of the newest methods developed for printing film and sheeting is valley printing (Fig. 8, p. 452), which consists of simultaneously embossing and printing. In one operation, the color is furnished to the peaks of the embossing roll and deposited into the valleys of the embossed sheeting. Valley printing produces unusual two-tone effects in elaborate floral designs and simulation of fabric surfaces. This new decorative technique offers a refreshing approach to decoration of vinyl sheeting.

Rubber rolls must be used to furnish ink to the high points of the embossing roll, restricting inks to alcohol- or water-soluble types. The ink is applied to preheated film or coated fabrics and maximum adhesion and water resistance is developed after aging for several days. Water inks have proved more resistant to cleaning solutions and general wear.

Transfer printing

A method consisting of printing on a carrier material and then transferring the print to a film is called transfer printing. It is normally accomplished by printing

It's Dangerous to have all your eggs in one basket!

Placing all your orders like neatly-arranged eggs into one basket is begging for trouble in this day of tight production schedules. If you depend on prompt delivery of rigid cast acrylic sheets to keep your production wheels turning, an additional source of supply is as essential as your machinery. More and more firms throughout the country find the Cast Optics Corporation a reliable source of Cast Acrylic Sheets — whenever they need them and in any quantity they want. Cast Optics Corporation specializes in producing optically clear, rigid plastic sheets of the highest quality — durable, abrasion resistant and cast to closer thickness tolerances. Get in touch with us today!

We are manufacturers...
not jobbers
of Rigid Cast Acrylic Plastic Sheets

Thicknesses .030 - .500 **Sheet sizes up to 48"x72"**
First grade or S-grade available in clear or translucent white
CR39 — ideal for instrument windows and other uses. If you are a fabricator, jobber or end user, contact us for immediate delivery from stock.

CAST OPTICS CORPORATION
300 Newman St., Hackensack, N. J.

Manufacturers of COCOR • BRAND Plastic Sheets

COCOR® Registered Trademark of Cast Optics Corp.

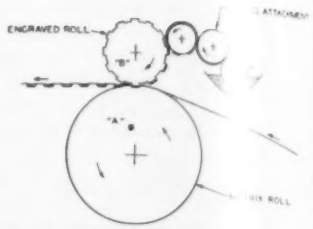

Fig. 8: Valley printing produces unusual two-tone effects

either a single or multi-color design on a special paper coated with methyl cellulose, melamine- or urea-formaldehyde resin, or an alkyd. The printed paper is placed in intimate contact with a film or is used as a surface onto which a film is cast. In either case the print releases from the paper and becomes an integral part of the film. The film, when stripped from the paper, bears the permanently transferred design. Special inks are used for ready print release. Excellent detail and register are obtained since the paper has minimum stretch.

Letterpress printing has limited use in the decorating of plastics film and sheeting, but is worthy of mention for its use in printing and decorating plastics credit cards, calling cards, and novelty items.

Stencil printing

The method of flat stencil printing is a hand or semi-automatic process and has the advantage that smaller yardages or short runs can be printed economically. Changing of the pattern can be executed more quickly than in the case of machine printing. The designs, usually ranging from 24 to 48 in. in repeat, are die-punched through a flat copper or stainless steel sheet which is attached to a rigid metal frame.

The fabric is pinned onto the padded surface of a long table and stencil printed in successive "strikes" at predetermined repeat "stops." Plastisol is fed into the unperforated border of the stencil which acts as a reservoir and is transferred through the openings in the stencil onto the fabric by moving the plastisol across the stencil with a hand-operated "squeeze" or scraper.

Multi-colored effects may be

obtained by using a separate stencil for each color of plastisol to be printed.

Screen printing, a form of stencil printing, is the oldest and least important printing method. The design is produced by passing the ink through unmasked areas of a silk or nylon bolting cloth mounted on a wooden frame. The main advantage of this method lies in the low cost of patterns or screens. This is offset, however, in large-scale production, by labor and handling requirements in that it is usually a hand process or, at best, only semi-mechanized.

Plastisol island printing

Discontinuous deposition of pigmented vinyl dispersions onto supporting fabrics of natural or synthetic fibers offers novel styling possibilities. The effective moisture-vapor transmission thus obtained (through the noncoated areas) also provides improved body comfort. Post-embossed graining, color topping of the plastisol islands, or the use of fabrics incorporating metallic or plastic yarns offer further design possibilities.

In the plastisol island printing process, the vinyl plastisol is deposited through the perforations of a flat metal, paper, or plastic stencil (*table printing*) or through the cut or punched perforations of a copper or steel cylinder (*continuous roller stenciling*). The thickness of the plastisol deposited ranges from 0.005 to 0.030 in. and normally covers from 50 to 75% of the fabric area.

The stenciled fabric is then passed through an oven for fusion of the plastisol. The temperature necessary is determined by the thickness of the deposit and the time it will be subjected to cure. Fusion temperatures generally range between 375 and 450° F. The supporting fabric, of course, must not be subject to distortion at the fusion temperature of the plastisol.

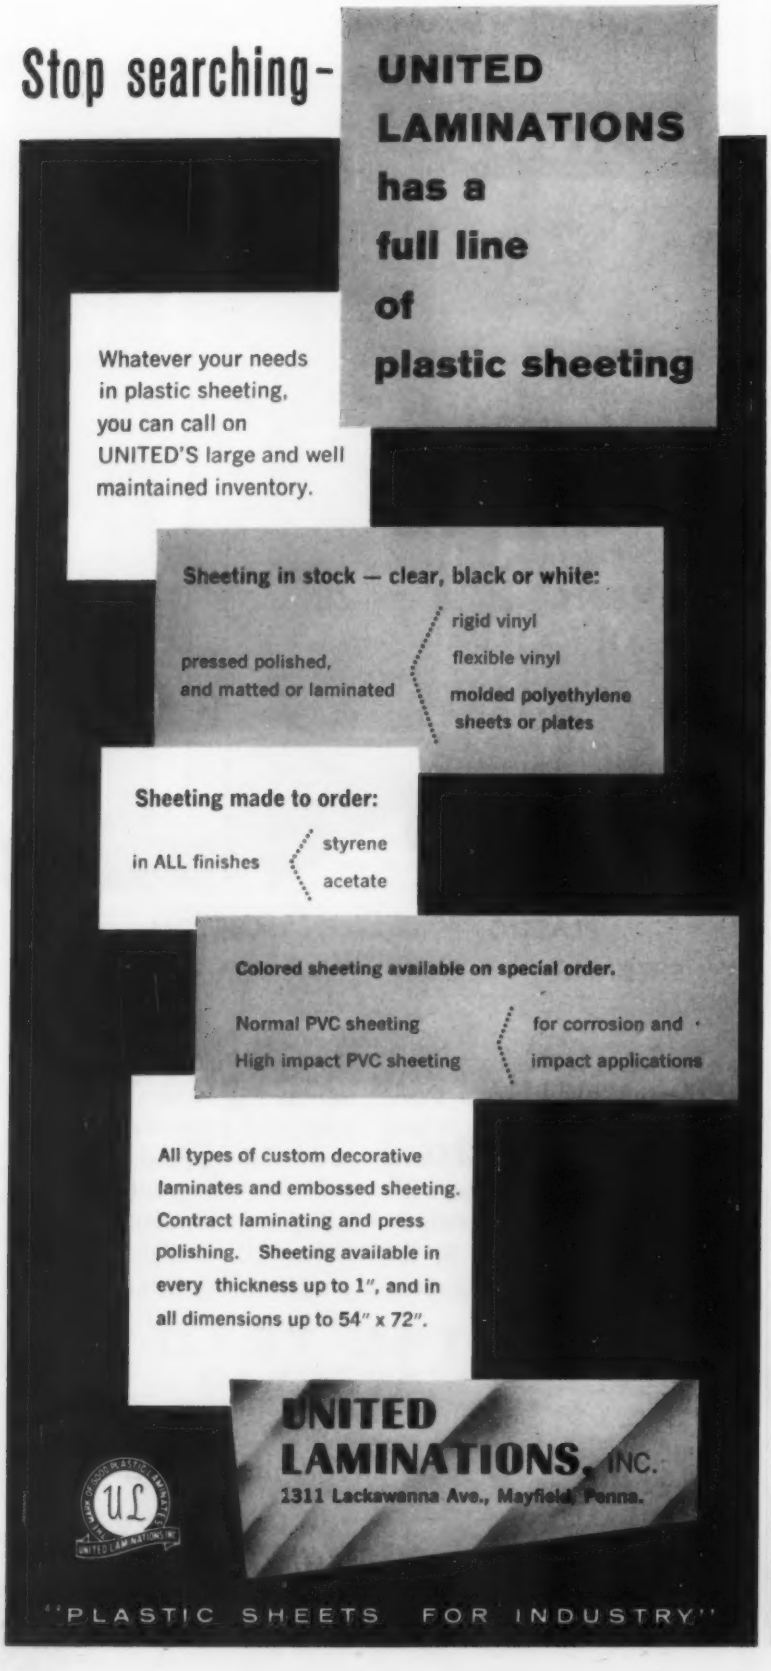
Top coating

In current practice, printed and embossed film and sheeting are coated with a clear resin solution principally to provide protection against wear and to promote cleanability. A wide range of

PLASTIC SHEETING IN STOCK

CUSTOM VACUUM MOLDING

Portage Plastics has plastic sheeting available in stock, in 6 colors, natural, white, yellow, red, blue and black. Orders on standard stock filled from inventory promptly. Minimum order of 50 lbs. accepted, gauges range from .010″ to .187″.



Portage engineers and designers will work with your sales and engineering staff in developing products from your own blueprints. Packaging and fabricating facilities are also available, PLUS plastic tubing from ⅛″ to ¾″ diameter.

For more information WRITE:

Portage Plastics Co., Inc.

MANUFACTURERS OF SHORECREST PLASTIC PRODUCTS

PORTAGE, WISCONSIN

gloss, semigloss, or dull finishes may be obtained. A series of solution-grade vinyl copolymers, acrylates, polymethyl methacrylates, butyrates, isocyanates, polyamides, and other resins are available to the film and sheeting converter for achieving the most desirable balance of properties such as controlled gloss, high flexibility, optimum wear resistance, cleanability, stain and perspiration resistance, lacquer marring, ultra-violet and chemical resistance, and antiblocking.

Clear protective vinyl or polyester (Mylar) films may be applied over decorated film and sheeting by lamination or by embossing-lamination techniques. The plastics industry is actively pursuing the development of a top coating that will increase abrasion resistance, prevent plasticizer migration, and expand the service life of vinyl film and sheeting.

Why Kodapak Sheet for window signs . . .

Signs printed on Kodapak Sheet by Goodren Products, Englewood, N. J.

The inside-outside story

WINDOW SIGNS printed in brilliant color on durable, clear-as-glass Kodapak Sheet are easy to see through—from inside or outside.

This means retailers can display them without hiding merchandise, without blocking the vistas of today's "open front" stores.

Little wonder retailers like them . . . use them . . . keep them doing their selling job.

Little wonder advertisers like them because *they do get used.*

And little wonder good sign-makers turn to Kodapak Sheet for this purpose. For Kodapak—uniform, stable, free from defects—provides an ideal surface for printing, keeps production costs at a minimum.

If you're interested in window signs or any of the hundreds of other uses for Kodapak Sheet, call our representative, or write.

STYRENE

Rubber-Modified Styrene Sheet

S-300 Styrene Sheet — A strong but lightweight sheet that can be made to take complex shapes by vacuum forming, or any conventional forming technique, with speed and economy on low cost dies.

S-540 Styrene Sheet — Is similar to S-300 but with exceptionally high impact resistance. Many applications in toys, displays, appliances.

Copolymer Styrene Sheet

S-1029 — An extruded styrene sheet with higher strength, greater color control. It has outstanding impact resistance *even at temperatures as low as —40F.* Copolymer also has high tensile and flexural strength, and a relatively high heat distortion point. Its chemical resistance is exceptional, particularly to acids and alkalis. Free from internal strain — it is readily vacuum-formed into complex shapes. Well suited to many applications such as machine housings, tote boxes, luggage, and photo trays.

All of these styrene sheets come in a wide variety of "built-in" colors. Finishes include mat, glossy, and new, simulated woodgrain. It's easy to paint, silk-screen or emboss.

CELLULOSICS

A-130 Cellulose Acetate — Noted for its strength and toughness. The sheet is excellent for vacuum forming. Ideal for blister packs. The film is used extensively in wraps.

B-120 Cellulose Butyrate — Has exceptional strength in thin sections . . . can endure long exposure. Applications in displays and outdoor signs.

E-100 Ethyl Cellulose — Highest thin-section toughness of all . . . maximum dimensional stability . . . minimum water absorption . . . light in weight.

new data on CAMPCO plastic sheet and film

POLYETHYLENE

Heavy Gauge Polyethylene Sheet — All conventional forming techniques can be used. Many housewares and packaging applications. We assist in experimental arrangements — various formulations, as your needs require.

Rigid Polyethylene Sheet — A brand new linear "low pressure" extruded polyethylene sheet, with excellent resistance to heat distortion — high rigidity and impact resistance, even in thin gauges. Highly inert — will withstand a wide variety of chemical attack, including some acids that even attack glass. Available in both Zeigler and Phillips types — in the same sizes and shapes as well-known S-300 and S-540 modified styrene. Excellent for many applications in both industrial and consumer products.

The range of CAMPCO applications is almost without limit. We would like to work with you in making the best use of these versatile materials. Write or phone today.

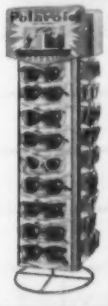
COMPLETE LINE OF FORMABLE SHEETING



come all kinds of less costly, more interesting products

NIXON MODIFIED VINYL
for a luxury look. Rich brown alligator grain is meticulously reproduced in this attractive display case for men's jewelry. Nixon supplies all types of vinyl sheeting with exceptionally fine forming characteristics, up to 54″ wide, in gauges from .005 to .040. *Pressure formed and constructed by Plaxall Inc., Long Island City, N. Y.*

NIXON CELLULOSE ACETATE
creates a sparkling, sales-appealing gift package for quality power tools. Provides visibility as well as protection. The durable .020-gauge Nixon sheet was *vacuum formed by Klear-Form Pak, Inc., Baltimore 30, Md.*

NIXON HIGH-IMPACT STYRENE
for sturdy, lightweight rotary counter display and sales dispenser. *Designed and vacuum formed by Mechtronics Corp., Mamaroneck, N. Y.*

NIXON CELLULOSE ACETATE, BUTYRATE AND NITRATE SHEETING, in a striking variety of colors and patterns, were used for the sunglass frames, *manufactured by American Optical Co., Chelsea, Mass.*

NIXON CELLULOSE ACETATE BUTYRATE
stands up under rugged outdoor conditions and takes well to all kinds of processing. This Indian head of Nixon butyrate sheet was first metalized to an eye-arresting "gold," then vacuum formed. Mirro-Brite butyrate supplied by *Coating Products, Englewood, N. J. Vacuum formed by Chanal Plastics Corp., Brooklyn 6, N. Y.*

NIXON HEAVY-GAUGE VINYL
speeds production, cuts costs and facilitates handling of television's scenic effects. Over 13½′ long, 18″ in diameter, this column weighs only 15 lbs. Old style weighs 150 lbs. *Vacuum formed by National Broadcasting Company Inc., New York, N. Y.*

NIXON ALSO MANUFACTURES RODS IN A WIDE RANGE OF MATERIALS, COLORS, SIZES.

SEILON!

SEILON is the Seiberling trade-name for a quality family of rigid thermoplastic sheets. You will find that SEILON is easy to form, easy to work, and can be welded with ease. We will be glad to send you complete information.

Seiberling Plastic Division is adaptable to customers' requests—and we will welcome the opportunity to consult with you on individual specifications of properties, gauges, colors and finishes for your products.

SEILON DESCRIPTIONS AND APPLICATIONS:

CR—Type I P.V.C. corrosion.

HI—Type II P.V.C. corrosion.

LC—Copolymer vinyl sheets for printing, laminating and vacuum forming.

FHI—High-impact copolymer vinyl sheets for printing, laminating and vacuum forming.

S-1—High impact polystyrene.

S-2—Super-high-impact polystyrene.

S-3—Tough thermoplastic material for vacuum forming.

DP—Corrugated or flat, polished or embossed, clear or opaque P.V.C. sheets for glazing and decorative applications.

ETH—Extruded polyethylene for vacuum forming, also for fabrication of corrosion-resisting equipment.

PLASTIC SHEET FOR THE VACUUM FORMING INDUSTRY

GILMAN NOW OFFERS

Stylour* — PLASTIC SHEET FLOCKED BEFORE FORMING

STYLOUR* is an amazingly versatile new material with almost unlimited application possibilities. Made of a special formulation, super high-impact styrene sheet, STYLOUR* is coated with a cotton or rayon flock which retains velvety-finish after forming. Available in a variety of brilliant colors and a wide range of thicknesses, lengths, widths and plastic finish combinations.

PLUS

GILCO **RIGID POLYSTYRENE PLASTIC SHEETS**

Extruded From Dow Styron®—Ideal For Vacuum Forming

All colors—all lengths

Widths to 52 inches

Gauges .010 to .250

Super High-Impact in either polished or matte finish. Specialized Translucent Formulation for lighting use. High-impact in polished or high-luster finish.

PLUS

GILCO **DECORATIVE SHEET**

First polystyrene decorated sheet. Available in numerous handsome finishes and colors of your choice. *Gilco Pelican Sheet* also in a scratch resistant finish that retains its original grain after forming.

PLUS

GILCO **POLYETHYLENE SHEET**

From .010 to .250 gauge in various formulations—low density, medium density and high density. In sheets or rolls up to 52" wide.

Fillers for Molding Compounds

BY RAYMOND B. SEYMOUR*

Fillers vary widely in composition, physical form, and cost. Their utility is determined almost entirely by the physical, chemical, and electrical properties of the product obtained by molding the mixture consisting of resin, filler, and other essential ingredients.

Impact values

Since fillers reduce brittleness (increase resistance to impact), phenolic molding compounds are often classified in accordance with the relative impact strengths of the molded products. Unfortunately, the impact values are usually based on the brittleness of notched specimens, even though the elimination of notches is a basic requirement for good plastics design.

In the absence of related end-use knowledge and experience, the published impact data are of limited value in the selection of specific types of molding compounds. At best, these values are relative. Hence, attempts to compare them often lead to erroneous conclusions.

As might be anticipated, a specimen molded from an A.S.T.M. Type 6 phenolic molding powder, having an impact value of 4.0, is less brittle than one molded from Type 2, which has a value of 0.24. It is erroneous, however, to state that Type 6 has an impact resistance 16 times greater than Type 2.

Impact values are very useful in checking quality and consistency within a general class of molding compositions. But it is incorrect to assume that different molding compounds with similar impact resistance values will exhibit comparable resistance to physical damage under actual conditions of use.

Obviously, other properties must also be compared in the selection of suitable molding compounds. When impact values are similar, it is essential that values for modulus of elasticity, flexural strength, and tensile strength be compared.

Types of fillers

As might be anticipated, many of the commercially used fillers are fibrous in nature. They may be naturally occurring minerals, such as asbestos, or organic materials, such as wood flour or cotton flock.

The organic fillers are sometimes classified as cellulose derivatives, lignin, protein, and carbon. These may be subdivided as shown in Table I, p. 470. Inorganic or mineral fillers are usually described generically.

Wood flour: Most of the wood flour used as fillers for molding compounds is obtained by attrition-type grinding of soft woods, such as Douglas fir, Norway fir, ponderosa pine, sugar pine, spruce, poplar, basswood, and cottonwood. The specific gravity of most soft wood flour when compressed is approximately 1.4. When equal parts of wood flour and resin are used, the specific gravity of the molded part will be approximately 1.35. Contamination from knots, bark, and resin spots must be kept at a minimum. Moisture should also be kept below 8% and preferably not over 5 percent.

Shell flour: When walnut shell flour is used in place of wood

Brotz, Plastics Engineering Co.; R. G. Booty, Booty Resineers, Inc.; R. W. Forbes, Barrett Div., Allied Chemical & Dye Corp.; A. W. Hanmer, Jr., Durez Plastics Div., Hooker Electrochemical Co.; W. H. Meadowcroft, Weyerhaeuser Timber Co.

Recent Developments and References were prepared by the editors.

flour molded parts with slightly lower resistance to impact and higher moisture resistance are obtained. Shell flour, as well as residues from furfural manufacture, may be used as an extender for resin glues, but there is no known significant use of these products at present in phenolic molding compounds.

Cotton flock: Cotton flock is used for the production of medium-impact molding powders. Such products exhibit slightly less shrinkage during molding than wood-flour-filled materials, but are more expensive and less readily molded.

Macerated fabric: Molding compositions containing chopped fabric have outstanding resistance to impact. These products are extremely bulky and are difficult to preform and mold. They are finding considerable use, however, when other products with normal impact resistance are not satisfactory.

Lignin fillers: According to the principal producer of ground fir bark, substantial quantities of this product are used by Eastern molding compound manufacturers. This product is also used extensively in the West as an extender for phenolic resin glues used in the manufacture of plywood.

It has been claimed that the flow characteristics of bark flour products make exceptionally high loadings possible. The producers of fillers derived from Douglas fir bark claim economies as a result of a decrease in resin content of the resulting molding powder.

These claims have been substantiated by experiments conducted in molding compound producers' laboratories. One of the leading producers of phenolic molding compounds for deep draw molding, however, has not been able to substantiate these laboratory results in actual production; this company found that the surface of the last third of the molded article was unsatisfactory whenever deep draws of 20 to 22 in. were attempted using phenolic molding compounds containing bark fillers.

Asbestos: The bulk of asbestos products used as fillers in phenolics molding compositions are classified as "floats." Molded asbestos-filled products have a high specific gravity and possess excellent resistance to heat and chemicals.

RECENT DEVELOPMENTS

A synthetic mica (*Synthamica 202,* Mycalex Corp. of America) is chemically pure, crystal clear, and comes in chunk, flake, and ground powder; it is a synthetic fluor-phlogopite and a true crystallographic analog of natural phlogopite mica. The principal difference between synthetic mica and natural mica, aside from its chemical purity and absence of discoloration, is the fact that the hydroxyl that is present in natural mica is replaced with fluorine, eliminating all possibility of the synthetic mica bloating or outgassing at elevated temperatures in a vacuum where trouble is experienced with the natural micas. The high thermal endurance of 202 makes it a very desirable material for high-temperature applications. It can be used as a high-temperature potting compound with a phosphoric acid treatment and subsequent high-temperature after-bake. The 202 product is also combined with glasses and ceramic binders to produce high-temperature ceramoplastic molding compounds sold under the trademark of Supramica.

A line of walnut shell flours, grits, and abrasives (*Stan-Shell,* Harwick Standard Chemical Co.) is available in a variety of mesh sizes. Fine nutshell flours are suggested for use as fillers for plastics and rubber and as extenders and fillers for phenolic resins. The coarser materials are used in air blast cleaning of molds and other products.

Manufacturing methods

Methods of manufacturing each of these fillers are as follows:

Wood flour is produced by a process that may be described as defibering rather than by cutting. Providing the size reduction is not too great, this attrition-type grinding preserves some of the original fiber structure. The typical fiber in 100 mesh wood flour is 0.004 in. long and has a cross-section of 0.00004 inch.

Shell flour is obtained by grinding various shells, such as walnut, pecan, or peanut shells. The product is somewhat spherical, rather than fibrous in form. Thus, the molded parts obtained have a smoother finish, but lower resistance to impact than those containing fibrous-type fillers.

Cotton flock is usually obtained by processing cotton clippings. A product with shorter fiber length is prepared by the caustic purification of cotton linters.

Alpha-cellulose is produced by an alkaline treatment of bleached wood pulp. Because of its pure white color and low density, it is used widely as a filler in urea and melamine molding powders.

Sisal fiber is generally used as a mat which is impregnated with a liquid phenolic resin. Prior to impregnation, the strength of the mat is usually improved by a needling process which drives tufts of fiber through the mass.

Chopped paper is usually impregnated with resin before being cut into fragments. Diced resin board is produced from sheet stock made from a suspension of pulp and resin.

Macerated fabric is produced by cutting various types of clean cotton cloth into small pieces.

Lignin fillers may be produced from the bark of trees such as Douglas fir or by extending wood flour with derivatives of lignosulfonic acid. Since lignin is the natural binder for cellulose in wood, the use of such products as partial replacement for resins in molding powders is possible.

Soybean meal is prepared by grinding the bean residue after the extraction of oil. When soybean meal is used as a partial replacement for wood flour, the molded parts exhibit poor resistance to moisture.

Keratin products, such as

  2) Carbon black

Inorganic (mineral) fillers

A) Asbestos
B) Mica
C) Diatomaceous earth
D) Chalk
E) Glass fibers
F) Miscellaneous: barium sulfate, litharge, clay, chalk, etc.

feathers, hoofs, or hog bristles, are usually calcined before use. These products, like lignin, permit a reduction in the amount of resin used in the molding powder.

Nylon, when used as a filler, produces a strong product which shrinks considerably during molding.

Naturally occurring *graphite* may be added to molding compounds in order to produce self-lubricating bearings.

Carbon black exhibits little reinforcing action in phenolic resins and actually contributes toward brittleness.

As would be expected, graphite and carbon blacks produce dark molded parts. Carbon black is used sometimes in small quantities as a pigment. The use of acetylene black yields molding powders with good electrical conductance.

Asbestos is a naturally occurring fibrous material obtained by cleavage of the mineral chrysotile—a form of hydrated magnesium silicate. Asbestos improves the heat resistance of molding powders, but increases the specific gravity.

Mica is obtained from the mineral muscovite, a complex potassium aluminum silicate. This filler is not readily wetted by the resin, but yields a molding composition which possesses excellent electrical properties and good resistance to heat.

Diatomaceous silica is an amorphous fossil consisting of the remains of diatoms. It has a lower specific gravity than asbestos or mica, but is not quite as effective as these fillers in improving heat resistance and electrical properties.

Glass fibers are produced by the extrusion of molten glass through tiny orifices. Molding compounds containing long-fibered glass have excellent resistance to impact and heat.

The inorganic compounds, such as *litharge, barium sulfate,* and *chalk,* are seldom used without other fillers. They contribute special properties such as high density and X-ray opacity.

Compounding techniques

Whenever the filler is available as a readily wettable powder it is generally mixed intimately in a ribbon blender with approximately an equal weight of phenolic resin previously compounded with other ingredients. When a two-stage resin is used, hexamethylenetetramine is also added as a curing agent.

The other ingredients, such as mold lubricants, dyes, pigments, and other finely divided powders, are usually present in small proportions.

The completely mixed formulation is usually passed between steam-heated rolls in order to secure a more intimate mixture and advance the resin. The compounded sheet is removed, cooled, and ground. The ground powder is then passed through sifting screens to remove the fines and tailings.

The portion with the desired screen analysis is then conveyed to a blender in order to secure large quantities of uniform products.

Some fillers such as coarse fibers and fabrics cannot be processed by conventional methods, since the shearing action would destroy the desired fibrous structure. Fillers of this type are usually impregnated with a solution of resin, diced, and then chopped into small particles.

The requirements for an ideal filler are as follows: 1) Yield strong molded parts with good impact resistance. 2) Inexpensive and readily available in uniform quality. 3) Low specific gravity in molded parts. 4) Low moisture absorption. 5) No deleterious effects on workmen or molds. 6) Readily wetted and require a minimum amount of resin. 7) Light color not affected by molding temperatures. 8) Odor-free and chemically inert. 9) Non-flammable. 10) Good thermal and electrical properties.

Properties of fillers

A critical examination of all known commercially used fillers will show that none is satisfactory

on all counts. However, wood flour meets many of the requirements and hence is the most widely used filler in phenolic molding compounds. Since color is considered more important than cost, alpha-cellulose is the principal filler used in light-colored urea and melamine molding compounds.

An examination of the empirical values assigned for various fillers in Table II, below, will give some idea of their general usefulness. Since the ideal filler would have a rating of 10 for all properties listed, its total index value would be 90.

Under the above specifications for an ideal filler, impact resistance is listed ahead of cost. However, there are some instances where resistance to heat is considered more important than either strength or cost. In such instances, the danger of drawing erroneous conclusions can be minimized by placing proper emphasis on those properties considered critical for specific applications. Each index value must be weighed in accordance with its relative importance for each end use.

With the addition of various fillers, properties can change radically. An unfilled phenolic, for example, has an impact resistance (ASTM D 256) of 0.25 ft.-lb./in. of notch, while a general-purpose phenolic (wood flour filled) has 0.30 and a high-impact phenolic (macerated textile filled), 2.0. Values for other materials are listed in the Plastics Properties Chart.

Typical applications

Molded products made from general-purpose phenolic molding compounds with wood flour filler include handles for appliances and cooking utensils, telephones, radio cabinets, house wiring devices, and automotive equipment, where moderate heat and electrical resistance is required.

Alpha-cellulose is used as a filler in most light-colored urea and melamine molding compounds. The molded products include appliance handles, switch plates, and tableware.

Medium-impact molding compounds containing cotton flock are molded to form washing machine agitators, hair dryer parts, and small industrial wheels.

High-impact molding compounds reinforced with macerated cotton fabric are used to produce heavy-duty industrial parts, such as pulleys and terminal blocks.

Appliance handles, heater plugs, radio condensers, tube bases, and similar articles requiring good resistance to heat and moisture are frequently molded from compounds filled with mica or asbestos.

Because of their exceptional versatility, thermosetting resins compounded with appropriate fillers have been used for the fabrication of thousands of different molded articles. These compounds lack the glamour of some of the newer materials and, like all good "work horses," are sometimes overlooked until no other satisfactory material is found. When "rediscovered," these time-tested plastics fill a real need.

Fibrous Glass Reinforcements

BY C. E. HOOVER* and RALPH SONNEBORN*

RECENT DEVELOPMENTS

In recent research for the Air Force (Owens-Corning Fiberglas Corp. for Wright Air Development Center), a 50% increase in modulus of elasticity of fibrous glass was achieved by the continuous formation of fibers of a calcium aluminate glass in a small textile glass bushing. Resistance of these glasses to chemical attack by water and water vapor is much less than that of commercially produced textile fibrous glass. The glasses are resistant to hydrofluoric acid but are completely soluble in hydrochloric acid. Their dielectric constants are higher than that of present textile glass, and the loss tangents are about the same as compared with textile glass.

All-glass "paper" (*Micro-Fiber paper*, Textile Div. of L.O.F. Glass Fibers Co.,) used as a surface material for reinforced plastics gives a more durable and smoother finish. The reinforced plastics have a high degree of resistance to erosion because the extremely fine fibers in the paper hold down the coarser fibers underneath.

Another glass fiber paper (*Dexstar*, C. H. Dexter & Sons, Inc.), made on a conventional paper machine, receives fine quality printing on its surface with no tendency of the ink which is used to bleed.

Flame-resistant epoxy resin-impregnated glass cloth (*Stanpreg*, Standard Insulation Co.), engineered primarily for critical electrical and electronic applications, is used in laminates with 83,000,000 megohm-cm. volume resistivity, 25,000,000 megohms surface resistance, and 18,000,000 megohms insulation resistance. The cloth is furnished in dry, nontacky tapes or rolls, and has uniform resin content, consistent optimum flow characteristics, and extended shelf life.

A new reinforcing material (*Lamimat*, Bigelow Fiber Glass Products) allows molders and laminators of reinforced plastics to achieve high flexural modulus at low cost with light weight. This drapable, uniform, lightweight mat with a blended organic-glass core and an all-glass face can be used to make thicker sections with high flexural modulus and considerably less weight than when using mats of all-glass fibers.

Glass is used in a wide variety of forms as a reinforcement for plastics. The availability of many types of reinforcement makes possible great design latitude in strength, rigidity, cost, production methods, shape, size, and directional characteristics.

The basic fibers are, in general, the same for all the various forms—mats, rovings, yarns, or woven goods. These basic fibers are formed from a lime-alumina-borosilicate glass that is relatively soda-free; it is commonly referred to as "E" glass. The individual fibers (filaments) are made in several diameters from 0.00020 to 0.00100 inch.

Fibers have many of the characteristics of bulk glass, but some properties are severely modified. Mechanical strengths are increased and the chemical resistance is reduced.

The tensile strength of glass fibers is about 400,000 p.s.i.; this value is independent of the filament diameter. The modulus of elasticity (E) is close to that of bulk glass—10,500,000 p.s.i. The modulus of resilience (the energy absorption characteristic) is increased a thousandfold by the fibrous form.

Fiber surface

The key to an understanding of the properties and processing methods regarding fibrous glass is held in the fiber surface. Glass is an inert material, but because of the extremely great ratio of surface area to volume (1 lb. of roving has about 880 sq. ft. of surface), a proportionally small amount of chemical attack is magnified into a significant quantity. Therefore, a really clean surface is almost a hypothetical condition.

A virgin fiber, at the moment of formation, is uncontaminated. However, within a few seconds, it has been superficially attacked by moisture from the air. When the glass is under load, this phenomenon can cause what appears to be fatigue. However, fibers of glass show neither creep nor hysteresis at room temperature.

Glass does not bond well with plastics materials. Consequently, the surface must be prepared for acceptance of a resin in much the same manner that some metals must be primed before being painted. Glass surface treatments are discussed later in this chapter.

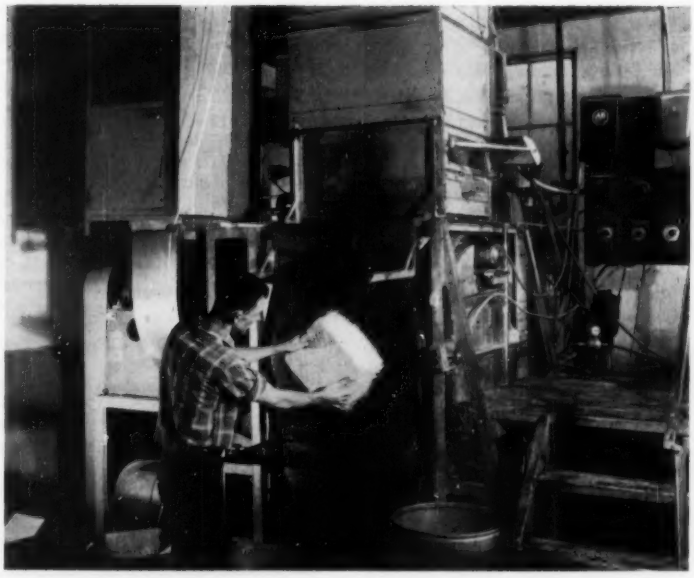
Manufacture of basic fiber

There are three basically different processes for manufacturing glass fibers: 1) steam or air blowing, 2) flame blowing, and 3) mechanical pulling. Most fibers used for the reinforcement of plastics are made by mechanical pulling. The two blown-fiber methods are used primarily for

* Owens-Corning Fiberglas Corp., 598 Madison Ave., New York, N. Y.

Recent Developments and References were prepared by the editors.

the manufacture of air filters, insulating materials, and staple yarns.



All these processes depend upon a small electric furnace with a number of metering orifices in the bottom. Molten glass flows through these orifices and fibers are attenuated from this molten stream. The bottom of the furnace which contains the orifices is known as a bushing. The design of bushings is very critical; because of the high temperatures involved, they often contain substantial amounts of the "noble metals."

Two methods are used to feed raw glass into the bushing: direct batch feed and marble feed. Direct batch feed consists of mixing the glass ingredients and melting them in a large gas-fired furnace. The molten glass then flows to the fore hearth where it is brought up to the proper temperature and is metered into the bushing. Where a marble feed is used, the molten glass is rolled into small marbles which can be shipped to the fiber-forming plant. These marbles are fed into the bushing on small tracks.

In the blowing processes, a jet of air, steam, or hot gas is directed at the molten stream. Short staple fibers are attenuated and become cool. Where extremely fine filaments are desired, a relatively thick "primary fiber" is mechanically pulled from the bushing and is in turn remelted and blown by a jet of extremely hot gas.

The mechanical pulling method produces a continuous fiber by mechanically drawing a filament from the stream of molten glass. During the early stages of cooling, the stream is attenuated into filaments by being pulled at very high speeds, normally in the range of 5,000 to 10,000 ft./minute. Depending upon the pulling speed, the orifice size, the molten glass temperature, and other variables, the filaments have a diameter from 0.00020 to 0.00075 inch.

For efficient production a number of filaments are formed simultaneously, one from each orifice in the bushing. These filaments are collected into a bundle known as a "strand" at a gathering device where a surface-treating material called "size" is applied. Below this is a winding apparatus which winds the strand into a forming package.

In one type of operation for making fibrous glass preforms for molding, glass roving feeds into a plenum chamber at the top of the machine where it is chopped into short fibers that are then deposited on mandrel. (Photo, Structurlite)

This basic forming package, often known as a "cake," consists of one strand (usually made up of 204 filaments) wound onto a flexible tube. The forming package is rather delicate and hence is merely an intermediate product from which the shippable forms of glass are produced.

Glass surface treatments

The glass filaments are very susceptible to abrasion from one another. Consequently, immediately after forming, a lubricant must be applied. Also, it is necessary to bond the filaments together in the strand; otherwise, they cannot be handled in subsequent operations without becoming very fuzzy. As described above, resins do not adhere to the glass, so an intermediate material known as a coupling agent must be applied to provide adhesion. Thus the surface treatment must serve three functions: 1) lubricant, 2) adhesive or bonding agent between filaments, and 3) coupling agent (a primer).

In the manufacture of certain types of reinforcements (yarns and woven fabrics), the glass is subjected to a great amount of abrasion. Consequently, the demands on the lubricant are great. It is unfortunate that the most effective lubricants act as a deterrent to the resin-to-glass bond. In the manufacture of these materials, therefore, it is necessary to sacrifice the coupling action of the size in order to get sufficient lubrication action. As a result, molding resins will not bond well to the yarns and fabrics, so it is necessary to burn off (heat-

Styrene molding compound for slide viewer housing has chopped glass as reinforcement. (Photo, Owens-Corning)

clean) the size after the weaving is accomplished and then apply a coupling agent. This coupling agent is known as a "finish." Two general types of finishes are used: silanes and "chromes"; the choice is dictated by the strengths required, the costs permitted, and the type of resin to be used (Table I, right).

In the manufacturing of some types of reinforcements (mats, rovings, and chopped strands), the fibers are not subjected to rigorous abrasion. In their processing, it is possible to apply a size that fulfills all of the three requirements. These sizes give good coupling action so that no heat-cleaning and finishing operation is required. Since this extra step in the manufacture is eliminated, these reinforcements are generally lower in cost than those that are finished.

These plastic-compatible sizes contain the same type of silane or chrome materials as is used in the finishes. The amount and type of bonding agent and lubricant can be varied to give a range of "hardness" and "fuzziness." In general, the type of coupling agent is dictated by the strength requirements of the molded part and the bonding agent is decided by the molding techniques to be used.

TABLE I: Types and sources of finishes for fibrous glass

Chopped strands

Strands can be cut into short lengths for use in the manufacture of molding compounds. They are made by passing continuous strands from the forming package through a cutter which chops them into predetermined lengths, usually from 0.5 to 2 inches. Available as bulk fibers, usually packed in bags, they are a low-cost form of reinforcement.

Rovings

Rovings are another low-cost reinforcement. They are used primarily in the preform process, and commonly in the manufacture of rod stock, as well as for local unidirectional reinforcement. Several fabricators also use rovings for the manufacture of chopped strand mats, and some cut the rovings into fibers for molding compounds.

Rovings are made from "cake" packages. A number of continuous strands are wound on a tube to form a cylindrical package; the number of strands can be varied—usually 60 "end" rovings are made.

Spun roving

"Spun" roving is a newly developed, potentially lower-cost form. It consists of one single continuous strand that is looped and wound into a roving-like form. Chopped spun roving is widely used in some forms of molding compounds. Preforming of spun roving has been difficult because of a tendency to stay in clumps, but this has been largely overcome by cutting to no greater than 1-in. lengths, and by breaking up the clumps. This is done by means of a special "spinner" design.

Reinforcing mats

Nonwoven mats are made of either chopped strands or swirled continuous strands that are laid down in a random pattern. The strands are held together either mechanically by stitching or "needling," or by means of adhesive resinous binders. They are available in many thicknesses, usually described in terms of weight/sq. ft.; mats can be obtained in weights from 0.75 to 10 oz./sq. foot.

Mats are lower in cost than woven materials, but are slightly more expensive than bulk chopped strands or rovings. The cost will vary according to the weight and bonding method employed.

The chopped strand mats are made from the basic forming package or from roving. The continuous strands are cut to a predetermined length (sometimes mixtures of lengths are employed) and are dropped or blown onto a forming chain. When resinous binders are used, the mat is passed through a curing oven after the binder is added and then onto the roll-up section of the machine. The mechanical needling for bonding, where used, is done immediately after formation of the mat.

The mats made from continuous swirled strands are formed directly from the fiber-forming bushing. The strand as it is formed is thrown on a moving conveyor. The resinous binder is then applied and the mat passes through a curing oven and into the roll-up section.

All these mats give essentially the same degree of reinforcement to plastics. Their major difference lies in their "handling" characteristics. Needled mats are soft and drapable and are available in heavy weights. The bonded mats are somewhat stiffer, but are stronger. The continuous strand

mats offer greater drawability; that is, they can be molded to more complex shapes than the others without tearing.

Milled fibers

Continuous strands from basic forming packages can be hammermilled into small modules of filamented glass. These fibers are available in nominal lengths from 1/32 to 1/4 inch. They are used largely for anticrazing filler reinforcement in casting resins and in resin adhesives where they give greater body and dimensional stability to the adhesive.

Yarns

Yarns are made on standard textile equipment from the basic forming package. Although primarily an intermediate material in the manufacture of tapes and fabrics, they have been used for rod stock. However, because of lower cost, rovings have largely supplanted yarns as a direct reinforcement for plastics. When yarns are used, they must be heat-cleaned and finished in order to get proper resin-to-glass adhesion.

A form of yarn is the warp beam, in which many parallel yarns are wrapped on a mandrel. This form is not in widespread use, but is a more convenient form for handling a large number of yarns for use as unidirectional reinforcement.

Surfacing and overlay mats

Where the smoothest possible surface is desired on a molding, thin mats of staple monofilaments can be placed over the reinforcement. These mats offer practically no reinforcing, but stabilize the surface resin and allow a heavy resin layer to be used. These mats range in thickness from 0.010 to 0.030 in. and have resinous binders that include treatments for maximum water resistance. Unlike the reinforcing mats, they use filaments of glass that are not collected into bundles. They are made either by the blown-fiber process or by mechanical pulling onto a large drum. These mats are available with a silane treatment for use where water resistance is especially important.

The difference between surfacing and overlay mats is basically in the stiffness of the material. Surfacing mats contain enough binder to make them quite strong; consequently, they are rather stiff. As a result, they are useful as a surfacing material only on flat or

TABLE II: Standard cloth constructions

Style	Warp yarn	Filling yarn	Construction	Thickness	Weight	Breaking Strength — Warp	Breaking Strength — Filling	Weave

simply-contoured parts. The overlay mats have a small amount of binder so that they are fluffy and extremely drapable. Although not as easy to handle as the surfacing mats, the overlay mats can be used on complex shaped parts.

Woven fabrics

Fabrics were the first type of reinforcement employed. Although higher in cost than mats, they are widely used because they impart high strengths.

Many kinds of fabrics and tapes are available. These vary in weight, thickness, style of weave, coarseness of yarns, and glass fiber diameter. Although both continuous and staple yarns are used, the continuous type is most common because of its higher strength. Because of the wide variety of fabrics available, almost any degree of thickness and directional properties can be obtained. Although most fabrics are "square" (an equal amount of glass runs both ways), unidirectional varieties are popular.

Yarn nomenclature

The nomenclature of fibrous glass yarns differs from that used for other types of textile fibers because of the large variety of nearly identical yarns that are produced. The complete nomenclature consists of two basic parts —one alphabetical, the other numerical. A series of three letters describing the basic glass strand is used in combination with numbers that identify the standard yarn count and yarn construction; for example, ECD 450-3/2. The first letter to be used defines the glass composition—"E" for electrical and "C" for chemical. The "E" glass formula, which is used most often, has excellent electrical properties while the "C" glass is compounded for chemical resistance and is used predominantly for certain types of staple fibers. The second letter indicates the type of fiber—"C" for continuous filament and "S" for staple fibers. The third letter defines the average fiber or filament diameter from which the yarn is made. The numerical values for the third letter are as follows:

D	0.00023 in.
E	0.00028 in.
F	0.00033 in.
G	0.00038 in.

Thus the letter symbol, ECD, given above, indicates a yarn made from the electrical glass formula in continuous filament form with an average filament or fiber diameter of 0.00023 inch.

The numbers following the letters indicate the hundred yd./lb. and yarn construction. The first number (count), 150, 450, 900, etc., is 1/100 of the approximate yardage of basic strand or sliver in one pound. Thus, yd./lb. is easily computed by multiplying this

Nonwoven mats are made either of chopped strands or swirled continuous strands. (Photo, Owens-Corning)

TABLE III: Comparison of reinforcements

		Reinforcing characteristics		*Applications*		
Type	*General description*	*Normal glass content %*	*Directionality*	*General use*	*Typical application*	*Relative materials cost*
Chopped strands	Bulk cut strands	35-45	Multi-directional	Molding cmpd.	Electrical components	Low
Rovings	Rope-like bundle of continuous strands	50-70	As desired	Preforming; unidirectional reinforcement	Machine housings; rod stock	Low
Reinforcing mats	Chopped or continuous strands in nonwoven random matting	20-45	Multi-directional	Parts with simple contours	Translucent sheet; truck body panels	Medium
Milled fibers	Bulk, small filamentized modules	2-10	Multi-directional	Adhesives and castings	Secondary bonding	Low
Yarns	Twisted yarns with after-finish	60-80	Uni-directional	Unidirectional reinforcement	Fishing rods	High
Surfacing and overlay mats	Nonreinforcing monofilaments in random matting	5-15	Multi-directional	To improve surface smoothness	Automobile bodies	High
Woven fabrics	Woven cloths with after-finish available in many styles	45-65	Unidir. or bidir.	High performance parts	Radomes	High
Woven rovings	Coarse, heavy fabrics	50-70	Unidir. or bidir.	High performance parts	Large containers	Medium

number by 100. The second series of numbers following the count number (−1/2, −3/0, −4/4, etc.) designates the number of plies in continuous filament yarns.

The first digit in this series shows the number of original singles (strands) twisted and is separated by a diagonal line from the second digit that indicates the number of these units plied. The total number of strands is determined by the products of these two numbers (0 is multiplied as 1). Plies in staple fiber yarns are shown by a single number separated by a diagonal from the count number.

Fibrous glass cloths are designated by a three letter symbol. The first letter designates the type of glass combination used—"E" for electrical, "C" for chemical. The second and third letters indicate the type of fiber used for the warp and the filling yarn, respectively—"C" for continuous filament, "S" for staple fiber.

Table II, p. 475, listing standard cloth constructions shows only those fabrics developed by Owens-Corning Fiberglas Corp. over a period of several years and currently in industry-wide usage in the electrical, industrial, and plastics fields.

In view of the normal trend in the textile field to develop lower-cost fabrics further to expand present markets and to develop new end uses, weavers have developed a complete line of fabrics using the coarser 150s filament yarns. These can be obtained in plain, unidirectional, satin, and twill weaves. Satisfactory performance, physical properties, and low costs make these fabrics ideal for reinforcement for plastics end uses.

Woven rovings

Woven rovings are a relatively new form of fibrous glass reinforcement, but they are becoming increasingly popular because they are thick, give high strengths to a part, and are lower in cost than conventional fabrics. Like the conventional fabrics, they are available in a wide variety of weaves.

Also known as "roving cloths," they are made by weaving rovings into coarse, heavy, drapable fabrics. Because they are made from rovings rather than yarns, heat-cleaning and finishing is unnecessary; the original size provides satisfactory resin-to-glass adhesion.

Woven fibrous glass rovings are thick, impart high strength to finished products, and are lower in cost than conventional fabrics. (Photo, Owens-Corning)

Economics

As already mentioned, there are significant differences in the costs of the various reinforcing materials. It can be stated generally that those forms that give the highest strength to a reinforced plastics part are the most costly.

The least costly forms (chopped strands, rovings, and mats) impart a nondirectional strength to the molded part. The more expensive woven materials are highly directional; that is, they give strength in one or two directions only. Therefore, a brief consideration of the strengths of panels would show that the woven materials are a much more efficient reinforcement.

However, this can be misleading because the strength of a part made with nonwoven reinforcements is spread in all directions and in many cases this is highly desirable. Also, the glass content of a part has a prime effect on the strength and, because of their geometry, woven reinforcements give substantially higher glass content than nonwoven reinforcements.

Nevertheless, on a cost-per-pound basis, a breakdown of the materials will show the woven fabrics, yarns, and surfacing overlay mats to be the most expensive. The woven rovings and milled fibers are less costly. The reinforcing mats are substantially low-cost reinforcements, while rovings and chopped strands are the lowest-cost forms that are available.

There are many reinforcements available for plastics. Each material offers a particular combination of handling characteristics, degree of reinforcement, and economics. Thus, choice of reinforcement has great bearing on the successful design of a reinforced plastics molding. (See Table III, p. 476, for a comparison of reinforcements.)

Synthetic and Cellulosic Fibers

BY H. R. SCHWARZ*

RECENT DEVELOPMENTS

Industrial fabrics (American Felt Co.), produced by mechanically interlocking synthetic fibers, have the physical characteristics of wool felt and the thermal and chemical properties of synthetic fibers. The felts have increased resin capillary absorption, greatly reduced surface fiber migration, high abrasion resistance, high impact strength, low moisture absorption, and low electrical conduction properties.

A copolymer of vinyl chloride and acrylonitrile (*Dynel*, Union Carbide Corp.) which is now used in overlays for fibrous glass laminates, improves weathering, reduces shrinkage problems, improves wetting properties, and is low in cost. The material is available in woven or nonwoven fabric in suitable weights for overlays. The surface not only improves abrasion resistance of the laminate, but improves resistance to chemicals and water damage.

Overlay-grade laminating papers impregnated with a new modified melamine resin (*Cyzac 2352*, American Cyanamid Co.) may be laminated directly to wood surfaces to produce, at moderate cost, a transparent, colorless finish with good surface properties. Printed laminating papers impregnated with another modified melamine resin (*Cyzac 2247*) are used in conjunction with the first resin to produce decorative surfaced hardboard for wall panels, door panels, cabinets, low-cost furniture, and TV cabinets.

A fire-retardant stretchable, cross-creped industrial paper material (*X-Crepe*, Cincinnati Industries) has been developed for lamination to vinyl film. The paper, available in roll or sheet form, can be stretched 15 to 60% longitudinally and 15 to 45% laterally. It can also be die-cut, sewn, or slit; fed from rolls into high-speed machinery; glued, cemented, or saturated; formed under heat and pressure; and embossed, indented, or printed.

Chemically shrunk acrylic (*Orlon*) felts available commercially (American Felt Co.) in weights ranging from 0.5 to 8 lb./sq. yd. are expected to have considerable application as overlays in reinforced plastics items.

Synthetic and cellulosic fibers—in nonwoven or fabric form—play an important role in the design of high-pressure or low-pressure laminates. The properties of the individual fibers which are commonly used for these applications are shown in Table I, p. 479.

High-pressure laminates: Cotton is the most important raw material used today for those high-pressure laminates requiring good mechanical properties such as high-impact strength, superior bond strength, and good machining properties. The fibers possess the very desirable combination of good strength and relatively low extensibility. They have the additional advantage of widespread availability and low cost.

Cotton fabrics are generally supplied as grey goods, that is, as they come from the loom, and are not subject to any wet finishing operations. However, they may in some cases be supplied desized or "purified." Desizing consists of removing the starch added to the warp to assist in the weaving operation, as well as the natural oils and waxes inherent in the cotton fiber. The term "purified" is used to denote fabrics which, in addition to being desized or scoured are bleached and thoroughly washed by water to remove any salts or electrolytes that might have a detrimental effect on the properties of the finished laminate.

Other textile fibers, notably nylon, have special properties that make them suitable for many useful laminated products. Nylon, for example, contributes to the laminate good electrical insulating properties, high impact strength, and resistance to bacterial attack. Rayon has found only limited uses in the high-pressure laminating field. High-tenacity rayon has been used for certain applications where high tensile strength is a factor. Acrylic fibers have also been used to a limited extent for electrical laminates.

Low-pressure laminates: Glass fiber is still, by far, the most important textile raw material in this field, whereas cotton has found few, if any, commercial applications, other than as an overlay material. On the other hand, filament nylon fabrics are being used successfully as reinforcements for low-pressure laminates designed as backing boards for bomber fuel cells. Nonwoven Dacron[1] batts used for reinforcing polyester and epoxy resins are said to contribute good abrasion resistance, in addition to improved electrical properties, more flexibility, and lighter weight. They are particularly suitable for the molding of deep-draw laminates since they readily conform to complicated shapes. A recent

development has been the use of Dynel[2] fabric overlays for glass-reinforced laminates. These overlays greatly improve resistance to abrasive wear, chemical attack, and weather. Acrylic fiber veils or overlays have also been used to provide an extremely smooth finish in automotive applications.

Acrylic, polyester, and nylon fibers are further being adapted as overlays to various materials-handling applications and end-products demanding good corrosion resistance. Synthetic fiber veil-covered surfaces offer improved chemical resistance, ultraviolet light resistance, good dielectric factors, and a harder surface.

Influencing factors

There are many factors involved in the selection of a textile fiber and fabric structure for a plastic laminate. It should be recognized at the outset that the fiber itself is the important element of the fabric contributing to the strength of a laminate (see Table I, right). When a continuous filament yarn fabric is used as reinforcement, the tensile strength of the laminate is influenced directly by the yarn strength. In the case of a laminate reinforced with a spun staple yarn fabric, on the other hand, neither the strength of the yarn nor the fabric itself has a direct bearing on the tensile strength of a laminate. It is the strength of the individual fibers which is the significant factor in the strength of the laminated product. The fibers in the spun yarn structure are surrounded by the resin which prevents them from shifting when stresses are applied to the laminated stock. Thus, the ultimate strength of the yarns themselves is never realized.

Another important factor having an effect on the laminate strength is the elongation of the fiber. Assuming that the elongation characteristics of the fiber and the resin are approximately the same, it is the fiber strength that is the determining factor within the limits of the effective adhesion between the fiber and the cured resin. To illustrate the importance of both strength and elongation in laminate strength properties, consider high-pressure laminates reinforced with spun nylon fabric. The tensile strength of nylon-base laminates is not as high as that of laminates reinforced with cotton fabrics. For, despite the higher strength of nylon, the fiber's lower modulus of elasticity does not permit the superior strength of the fiber to be fully utilized when incorporated in a rigid plastic structure. On the other hand, the fiber tenacity has a direct influence on the high impact strengths possessed by the nylon-reinforced laminates.

Fabric specifications covering textile materials for laminating purposes generally include minimum breaking strength requirements. One of the principal reasons, of course, is to insure uniformity of material. Fabric breaking strength can be easily determined by any textile laboratory. Provided minimum strength values are met in addition to other specification requirements, it is a definite indication that the fabric in question is up to standard.

Generally, plastics produced by laminating techniques are rigid, having a high modulus of elasticity. Accordingly, stretchability and resiliency normally associated with fabric structures formed by the interlacings of twisted yarns are not factors affecting the properties of the laminated material. These fabric characteristics, however, are significant in the case of textiles for postforming stock. Nevertheless, the particular form in which the fibers are introduced to the resin does have an influence on the ultimate properties of the laminate.

Types of fabric

Nonwoven fabric: Nonwoven fabrics or mats are generally made with random fiber distribution and

TABLE I: Properties of textile fibers

COTTON'S natural fiber twist enables spinning of strong yarns. Cotton is durable, absorbent, resistant to stretching and heat; it bulks and insulates well, has high wet strength. Resistance is low to acids and mildew, but high to alkalies and solvents.

RAYON, a regenerated cellulose in staple or filament form, is industrially most important in *high-tenacity* form, with outstanding qualities of high strength combined with light weight. Many of its other properties are similar to those of cotton, but wet strength is lower.

FORTISAN[1] is a strong filament yarn of oriented and saponified regenerated cellulose. The new, highly oriented "Fortisan-36" has exceptional strength, stretch resistance, and dimensional stability. Chemical and other characteristics resemble cotton.

NYLON is a chemically synthesized organic fiber, both staple and filament, available in high-strength forms. It has very high tenacity, wet or dry; excellent abrasion- and flex-resistance; toughness; elasticity; resistance to heat and alkalies; excellent electrical qualities.

ORLON[2] acrylic staple fibers are light, strong, resilient, dimensionally stable, low in moisture absorption and are nonconductors of electricity. They show good resistance to heat, strong acids, mildew, bacteria, ultra-violet rays, and atmospheric effects.

DYNEL[3], staple fiber of vinyl and acrylic origin, has many properties similar to Orlon. Though sensitive to heat, Dynel has excellent resistance to strong alkalies as well as acids, and will not support combustion.

DACRON[2], polyester staple fiber, is water-repellent, quick drying, dimensionally stable, with good electrical properties. It has good strength, flex life, and shape retention, and resists abrasion, heat, and many chemicals.

bonded with resins which are compatible with those used in the laminating process. Laminates made from the random nonwoven material have impact, flexural, and tensile strengths just as high in the diagonal directions as in the usual machine and cross-direction.

Nonwoven fabrics are used in the manufacture of laminated products requiring sharp projections or edges, mirror-like machined surfaces, and superior mechanical strength. An early application was the noiseless gear for electric clocks. The balanced strength characteristics of laminates with random fiber reinforcement made it possible to produce fine-toothed gears without weak spots in the teeth. High-speed machining of the laminates without damage was made possible.

Another good example of the unusually good mechanical properties of laminates reinforced in this manner is the textile bobbin head. Tests have shown that heads fabricated from these laminates have nearly twice as much impact-fatigue resistance as the next strongest type (paper-and-canvas-reinforced).

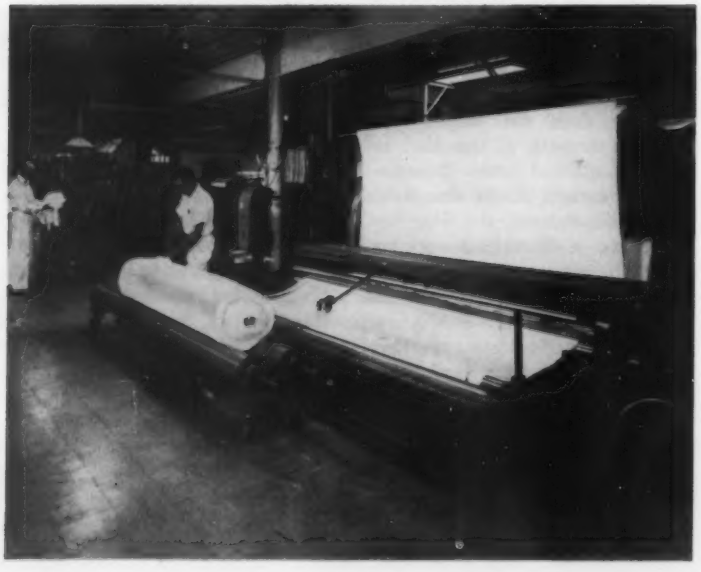
There has also been some activity in the use of papers based on synthetic and cellulosic fibers for reinforcing laminates, but most of the work in this area is still largely in the experimental stage.

Woven fabrics: The density and positioning of the individual fibers in the fabric structure must be considered in developing the optimum laminate to be used for a given application.

Fiber in fabric form has certain advantages which are utilized in laminating production.

Probably the single most important factor is the extremely uniform distribution of the fiber in woven fabrics. This high degree of uniformity enables the plastics manufacturer to combine many layers of varnished cloth together to form a laminate having a homogeneous structure. Furthermore, fabric has the advantage of mechanical strength, enabling it to be processed readily without damage by continuous methods.

Generally speaking, the laminating varnish has a better opportunity to penetrate the more porous structure of spun staple yarns than the more compact and denser filament yarns, especially in the case of the heavier-weight fabrics. In many cases, economic considerations necessitate the use of comparatively heavy fabrics for mechanical laminates, because of their lower cost per pound.



The amount of yarn twist has a definite bearing on the degree of resin penetration. Fabric woven from softly twisted yarns although not necessarily so strong from a textile standpoint, nevertheless, allows more resin to penetrate the fabric structure. This results in a stronger laminated product. Another influencing factor on the properties of fabric-base laminates is yarn crimp. Highest tensile strengths are realized by having the fibers lie as flat as possible in the plane of the laminate. In this position the full reinforcing effect of the individual fibers can be utilized to the best advantage. On the other hand, fabrics with a high yarn crimp tend to increase the shear strength of the laminate.

The effects of the various components must be carefully considered in the selection of a fabric construction for a particular end-use. In the majority of cases it is desirable to use a fabric having an equal distribution of strength in the warp and filling in order to obtain balanced strength characteristics in the laminated product. By cross-laminating, however, it is possible to use fabrics with unequal strength distribution and still obtain laminates with balanced properties. For certain applications it may be advantageous to have the strength largely in one direction; in these instances, so-called unidirectional fabrics are employed.

The bond strength of laminates, and by this is meant the adhesion between the fabric plies, is affected to an important degree by the surface characteristics of the fabric. A softly twisted spun yarn construction, presenting a fibrous surface and a high degree of fabric "pebble" or surface texture, results in an interlocking effect when the fabric layers are combined during the laminating process by means of heat and pressure. At the other extreme, a smooth surface, finely-woven fabric made from continuous filament yarns may have a tendency to delaminate easily. Therefore, a fabric of the latter type should not be used for those applications requiring a high degree of bond strength.

The tightness of weave, as affected by warp and filling yarn

Dacron fibers are made into batts in needle loom. Used as a reinforcement or an overlay, the batts are more drapable than bonded mats. (Photo, Troy Mills)

sizes and thread count, also has an effect on the laminate properties, particularly from the standpoint of resin impregnation. It is the combination of yarn and fabric structure that influences the properties of the final laminated product. The type of weave must also be taken into consideration in view of its effect on yarn crimp, porosity, and surface characteristics.

Types of weave

As an indication of just how many different types of weave are available to the laminator, listed below are definitions of standard cotton industrial fabrics based on generally accepted trade practice.

Lawns: These are lightweight, high-count staple fabrics made in plain weaves from both carded and combed cotton yarns, generally with yarn numbers 60s or finer.

Print cloth: Made from coarser yarns than those used in lawns, generally 30s warp yarn and about 42s filling yarn. Print cloths are woven in a large number of thread counts.

Sheetings: The term "sheeting" is applied to a plain-weave cotton fabric using carded singles yarns for warp and filling.

Drills: Drills are 3-harness twill constructions, made with the ends interlacing, 2 up and 1 down. Woven with carded singles yarns, the drills are available in a wide range of widths and constructions.

Osnaburgs: This term is applied to plain-weave fabrics which are of lower count and of coarser yarns than sheetings. They may be classified as "coarse sheetings." In count, they range from about 24 by 16 to 40 by 32.

Ducks: Cotton duck is a broad term used to denote a considerable range of firm, heavy, plain-weave fabrics. In the case of so-called flat ducks, singles warp yarns are woven in pairs. There are several general types of duck based on differences in construction as follows: a) duck in which both warp and filling yarns are singles; b) duck in which the warp yarns are singles and the filling yarns plied or twisted; c) duck in which both warp and filling yarns are plied or twisted.

Following are the definitions of certain types of cotton ducks that have found a place in high-pressure laminating.

Single filling duck: A flat duck of medium weight made from singles warp yarn, sized, two ends woven as one, and singles filling yarn.

Army duck: Army-type ducks are firmly woven ducks in which both warp and filling yarns are plied, free from added warp sizing. They are made in a wide range of widths and constructions. A standard army duck construction used for laminating would be 37 in. wide, 10.10 oz./sq. yd., and 54 by 42.

Numbered ducks: These are firmly woven, plied yarn ducks, made in a great variety of widths and constructions. The weights are designated by numbers, starting with a No. 14/0 weighing 32 oz. to the linear yard, 22 in. wide, all the way to a No. 12 duck, weighing 7 oz. to the linear yard, 22 in. wide.

Chafer duck: This includes a range of plied and singles yarn fabrics, usually constructed to provide an equal thread count and breaking strength in warp and filling. The weight range is from about 8 oz. to 17 oz. to the sq. yard.

Gear duck: Gear duck is so-called because it has had wide use in the manufacture of laminated gear stock. A wide variety of ducks, including single filling, army, and special plied yarn constructions, are used for this purpose and similar applications by the plastics industry. They are generally made to meet user's specifications.

Asbestos Reinforcements

BY D. V. ROSATO*

Asbestos reinforcements are available in a variety of forms, such as felts, mats, papers, asbestos molding compounds, prepared asbestos fibers, and cloth or yarn, and are used to provide, among other advantages, increased stiffness, heat resistance, chemical resistance, and insulation.

Some 30 or more minerals of fibrous crystalline structure comprise the asbestiform group, but only six have economic significance: chrysotile, crocidolite, amosite, anthophyllite, tremolite, and actinolite. The type of asbestos most commonly used in commercially available felts and mats is chrysotile, a hydrated silicate of magnesium. Felts and mats are available with all-chrysotile fibers or a combination of chrysotile fibers with cotton, rayon, or glass fibers. When a combination of fibers is used, lower mechanical properties are generally obtained. The principal purpose for combining fibers is to permit products with variations in properties which will be in direct proportion to cost of products. The all-chrysotile felt or mat makes available plastics with exceptionally high modulus of elasticity values. Values ranging from 5 to 6 million p.s.i. are obtained in the laminate.

Felts, mats, and papers

Asbestos felts and mats, (e.g., Pyrotex[1]), are composed of mechanically opened asbestos fibers which have been processed through carding machines that arrange the fibers in a tenuous web. The carding process is a basic step in the manufacture of practically all asbestos textiles. Sheet materials approximately 10 mils in thickness are referred to as "felts"; sheet materials with thicknesses greater than 10 mils are referred to as "mats."

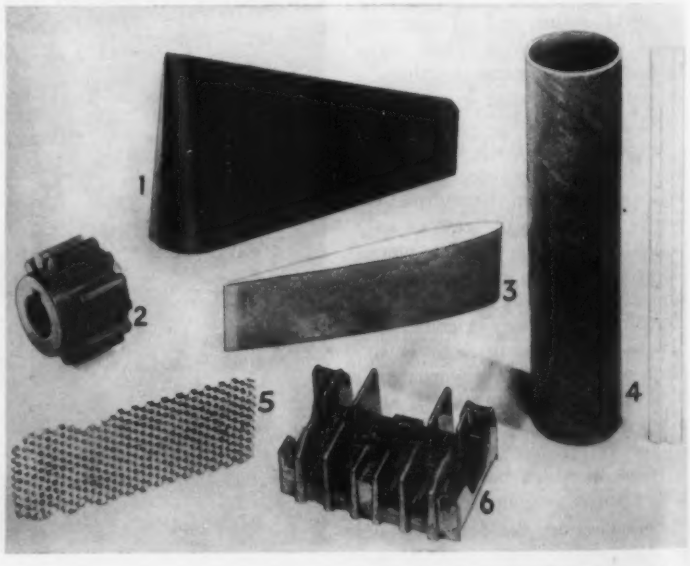
Asbestos papers (e.g., Novabestos[1]) are the result of a chemical process that produces dispersed, single, long-fiber asbestos. Products made with this material have an extremely fine, smooth, uniform, flexible, and long fibrous structure. They differ from commercial papers in that they contain no filler materials such as cement or reprocessed pulp.

Asbestos fabrics have been used successfully for a number of decades. Products have generally been made by high-pressure curing where electrical and/or mechanical requirements exist.

Processing

Standard reinforced plastics molding techniques can be used in fabricating asbestos-reinforced plastics. Felts are readily handled in wet or dry lay-ups. Felts containing no resin binder can be wet readily, but cannot be handled in large unsupported sheets.

Felts are also available with approximately 3 to 5%, by weight, of a binder which is compatible with all the different resins (phenolic, epoxy, silicone, etc.). These felts can be used in unsupported sheets. The ability of these felts to wet satisfactorily with resins and retain wet strength can be illustrated by the fact that they can be used in continuous laminating processes or put in vertical drying towers for the purpose of making prepregs. Felts with binders can be sent unsupported through 60-ft. vertical towers.



Bulk factor of felts or mats is approximately 3 to 1 when curing pressures of 400 to 500 p.s.i. are used. The ratio is 3 to 2 when curing pressures are 10 to 50 p.s.i.

In parallel lay-ups using asbestos felts or mats, the physical properties are in the ratio of 3 to 2 when going from the longitudinal to the transverse direction. The longitudinal direction is the machine direction of product. These products can be oriented in various patterns in order to produce laminates having varying directional properties. To obtain an isotropic sheet (properties the same in all directions in the plane of the sheet), the felts need only be laid up 90° to each other.

Asbestos molding compounds

Asbestos fibers are used as reinforcements or fillers for molding or premix compounds. These

Applications for asbestos-reinforced plastics include: 1) missile fin; 2) pinion gear; 3) airfoil section; 4) rocket launcher body tube; 5) honeycomb core; and 6) electrical switch gear. (Photo, Raybestos-Manhattan, Inc.)

* Chief Engineer-Product Mgr., Reinforced Plastics Dept., Raybestos-Manhattan, Inc., Manheim, Pa.

References were prepared by the editors.

[1] Trademark of Raybestos-Manhattan, Inc.

molding compounds include various types of resins (polyester, epoxy, melamine, etc.). Molders use fibers to improve or obtain the following characteristics: dimensional stability; elimination of gloss on surface; impact; chemical resistance; flow of molding compound, in use with or without other reinforcements; reduced warpage; heat and flame resistance; durability; and lowered cost of compounds.

For certain applications, asbestos sheet materials require filler material in order to take care of nonuniform cross-sections. Asbestos-phenolic resin molding compounds are available that can be used for such purposes in conjunction with sheet materials or alone.

Asbestos preforms

Basically, two types of preform machines are in use. One is equipped with an automatic cutter which cuts roving at a uniform rate. The cut roving in turn is deposited on a preform screen. Chopping equipment differs from that used with fibrous glass in that glass choppers need only "bend" glass, whereas asbestos has to be "cut." The second machine is a "blown" preform type in which prechopped glass and asbestos fibers (with or without resins) are blown through a hose onto a preform screen.

Other types of machines and techniques involve preparing a slurry or water mixture which contains asbestos, etc. A perforated screen dipped into the slurry has asbestos, etc., dispersed on it when removed. Drying and resin treatment then follow this operation.

Laminate properties

The physical properties of laminates are largely dependent upon the type of mold, molding pressure, and the asbestos-resin ratio. These characteristics are similar to those found in other types of reinforced plastics. The flow characteristics of laminating resin contained in treated felts or mats should be established to coincide with the molding or laminating pressure and techniques to be employed. The resin flow is determined by weighing 4-in. squares

CORDOPREG® + MOBALOY®

NEW PREPREG PRODUCTS FOR AIRCRAFT, MISSILES, ROCKETS

Quality-controlled pre-impregnated glass fabrics and uniform tension rovings available with these stabilized CORDO RESINS:

- **POLYESTER**
- **SILICONE**
- **EPOXY**
- **DAP**
- **HIGH TEMPERATURE PHENOLIC**
- **HIGH TEMPERATURE EPOXY**

approved and specified by leading manufacturers for aircraft, guided missiles and rocket components.

CORDOPREG + MOBALOY offers outstanding advantages to the molder, as it may be easily and rapidly handled in die cutting and press loading and is ideal for automatic processing.

CORDOPREG + MOBALOY virtually eliminates waste, assures consistently high quality with increased press output, and lowers tool and overhead costs.

CORDO leadership in research and development is available for economical, accurate evaluation of new applications. Write for catalogs and full information.

SOLKA®-FLOC

Pure, Finely Divided Wood Pulp

A versatile formulating aid that gives strength to your plastics molding compounds

Solka-Floc* is a chemically pure wood cellulose, non-abrasive and relatively inert to acids, alkalis and solvents.

Through its use as a formulating aid you can obtain strength, heat stability, improved wear when used with phenolic, urea, melamine and polyester resins.

Solka-Floc is available in a wide range of grades and prices to meet your specific requirements. For samples and details on how Solka-Floc will benefit your product, write Dept. FL, at our Boston Office.

*Available in Canada from Brown Forest Products, Ltd., Montreal (Alpha Floc)

BROWN COMPANY

Berlin, New Hampshire

General Sales Office: 150 Causeway Street, Boston 14, Mass.

(approximately 25 g.) before and after pressing for 5 min. at 300° F., under 400 p.s.i. pressure.

Asbestos felts and mats are specifically tailored for high physical, electrical, and/or high-temperature applications. Typical parts using these products are missiles, rockets, aircraft structures, firewalls, electrical generators, turbine wheels exposed to heat, radomes, flame-resistant paneling, honeycomb construction, heat-resistant decorative paneling, etc.

Types of laminates

Asbestos-phenolic laminate: To date, the majority of the work involving asbestos felts and mats has been with phenolic laminating resins. Asbestos-phenolic laminates can be used at elevated temperatures. Parts have withstood temperatures of 2500° F. for 60 sec., and 3500° F. for 6 to 10 seconds. Parts requiring low strength have been used in continuous exposure to a temperature of 300° F. for periods of at least 1 year. Where thermal insulation was of prime consideration, these products have been subjected to 5000° F. for short periods. Where dimensional stability of parts is required, these products are useful. Laminates and molded products have been subjected to temperatures of 300 to 350° F. in dry or wet steam with relatively no change in dimension or strength.

To develop maximum strength, parts have been postcured for different cycles of time and temperature ranging from 1 to 5 days, and 250 to 500° F. Time and temperature cycles for postcuring depend on thickness and shape of part. If blisters or delamination occur during the postcure, increased curing time at lower temperatures or longer press cure cycle is recommended. Postcuring need not be conducted with parts in press mold. For requirements where initial strength does not have to meet maximum properties and it is desired to subject parts for long periods of time at 300 to 350° F., no postcuring is recommended.

Asbestos - silicone laminates: Felts impregnated with silicone resin produce exceptionally heat-resistant laminates or moldings. As an example, 5 to 10 hr. ex-

Creative papers from the mills of MOSINEE

Mosinee's wide experience in working with major plastics manufacturers may pay off for you. For years their research and development departments have been custom-designing paper to suit specialized plastics applications.

In the plastics industry...

low-cost papers replace expensive traditional materials

Offering a combination of economy and versatility, Mosinee creative papers are proving their worth throughout industry. These special sulphate papers are being used where paper was never before even considered. And they're performing as well or better than the more costly materials previously used.

With scientifically controlled processes, Mosinee can produce papers possessing an amazing variety of chemical and physical properties including high dielectric strength . . . mold, flame, water and corrosion resistance . . . resin holdout or absorbency. Especially important, Mosinee can quantity-produce these papers with dependable uniformity.

HERE ARE 6 GOOD REASONS FOR CALLING ON MOSINEE FOR YOUR SPECIAL SULPHATE PAPERS:

1. A proven record for creating outstanding custom-tailored papers
2. Extensive research facilities
3. Specially developed quality controls
4. Nearly 50 years of experience
5. Technical consultants in your area
6. Flexible production capacity

Chances are Mosinee may already have answers to fabricating, processing or packaging problems you are now working on! Mail the coupon below for more complete details.

posure of these parts at [illegible]° F. produces relatively no [illegible]sual change and the parts reta[illegible] their strength properties.

Heat resistance

Being a mineral, asbes[illegible]os has great heat resistance, and [illegible]n be heated to high temperatures without burning. This is one of the major reasons for its use in reinforcing plastics.

When asbestos is combined with various resins, its behavior cannot be directly related to asbestos alone. As an example, asbestos-phenolic laminates, when subjected to 5000° F. for a short period of time, will retain mechanical strength properties; asbestos alone would retain very little of its strength properties. However, the fact that asbestos alone can be subjected to temperatures above 2500° F. without complete decomposition or melting enables asbestos-reinforced plastics to retain a good portion of their strength at elevated temperatures when combined with heat-resistant resins.

Applications

Asbestos felts and mats are specifically tailored for high physical, electrical, and/or high-temperature applications. Typical fields of interest for these materials include: missiles, rockets, aircraft structures, firewalls, electrical generators, turbine wheels exposed to heat, radomes, flame-resistant paneling, honeycomb construction, and heat-resistant decorative paneling.

Plymouth Cotton Flock and Filler for plastics reinforcement

● Even in strong sunlight, you can see that Plymouth cotton flock and filler is spotlessly clean. In fact, it is recommended as a filler in thermoset dinnerware and other products where CLEANLINESS and IMPACT strength are vital.

Plymouth flock and filler is always completely *uniform*, assuring you of products with full, *lasting* impact strength.

Plymouth cotton flock and filler is made from the finest, selected 100% cotton materials, carefully reduced to the precise size your particular product requires. This careful grading process, plus "sunlight cleanliness," makes Plymouth cotton flock and filler a superior one.

Test Plymouth flock and filler in your own plant. Write for samples and full details.

How to test for ADVERTISING IMPACT in the plastics field

If you have anything to sell ... chemicals, materials, machines, or equipment ... that the fast-growing plastics industry can use, now is the time to establish your company firmly in the plastics market. In 1956 material production reached the four billion-pound level ... and the outlook is for continued expansion. The place to start your sales program is in MODERN PLASTICS, *the one plastics magazine that stands up to this 3-way check for maximum advertising impact:*

CHECK THE CIRCULATION: The 29,000 distribution of MODERN PLASTICS includes the *largest paid* circulation covering the two basic areas of the plastics market. These are:

1. the plastics industry itself—(a) the processors who mold, extrude or otherwise fabricate plastics materials into products and parts; (b) the plastics materials suppliers.

2. the "end users" of plastics in many different industries—who incorporate plastics components in the products they make. (Soon as their volume is big enough, they often set up "captive" plastics plants, or buy out existing plants and incorporate them into their own operations.)

Because MODERN PLASTICS plays a major role in the field's continuing growth, because it is constantly in the vanguard of new product explorations, it is today the recognized voice of these plastics converters and users. As a result, it's literally "the" plastics magazine, with a record-high, all-paid circulation that has matched the market's growth stride for stride since the industry's infancy.

CHECK THE EDITORIAL INFLUENCE: MODERN PLASTICS is the overwhelming choice of executives with buying authority. For example, a Starch survey* made at the 1954 National Plastics Exposition showed that MODERN PLASTICS gives these men more help than all other magazines in the field combined!

The *editorial aim* of MODERN PLASTICS is to increase the use of plastics materials throughout industry ... wherever they fit the job. It serves all facets of the field ... the makers of plastics, the processors and the manufacturers who use plastics in volume, in products of all kinds.

Almost two-thirds of its actual paging is devoted to stories of new trends, new applications, new areas of expansion. The rest is almost equally divided between plastics engineering and production methods ... and the technical problems of plastics chemistry and testing.

CHECK THE ADVERTISING: More advertisers spend more money and use more space in MODERN PLASTICS than in all the other plastics magazines. What do they sell? All this:

Chemicals and Materials—adhesives, synthetic resins, plasticizers, coatings, emulsions, colorants, extenders, fillers, laminates, saturating papers, stabilizers, solvents, wetting agents.

Machinery—hydraulic systems, molding presses, accumulators, granulators, calendars, heat sealers, polishers, slitters, mills, mixers, motors, hobbing presses, embossers, pyrometers, scales, timers, cutting tools, drills, duplicators, lathes.

Services—industrial designing, molding, fabricating, laminating, embossing, hobbing, deep drawing, decorating, postforming, mold making, extending.

Every test will tell you—MODERN PLASTICS has what it takes to help you develop orders for anything you're selling to the plastics field...whether it's or supplies, machinery or services!

*Write for the full report of the Starch survey and for 40-page market data file.

MODERN PLASTICS ENCYCLOPEDIA ISSUE

12 months of effective selling...with a single ad

This is the standard "how-to-do-it" reference work of the plastics field, published once a year (in September). It is packed with vital information ... used the year 'round ... includes a 110-page Buyers' Directory, Plastics Properties Charts, a report on current developments in plastics materials, operating procedures, engineering and methods, and technical data.

IT SELLS! A comprehensive personal-interview study shows the average reader refers to it 40 times a year. Seven out of ten say they bought products as a direct result of using the Encyclopedia.

Annual closing date: June 20th.

FABRICS - FINISHES - IMPREGNATIONS

impregnated fabrics

Quality glass fabrics woven, finished, impregnated under our exclusive one-company operation. Consistently uniform products for general purpose and high temperature-high strength uses. Standard and custom systems in phenolic, silicone, epoxy resins. Available chopped for matched die molding.

finishes and impregnations

World's most up-to-date facilities for impregnation of natural and synthetic fabrics, felts, paper and asbestos. Plant accommodates widths up to 72". Standard and custom finishes and impregnations. Research and development facilities available to work with your engineers on new materials.

boat fabrics

Fiberglass fabrics for glass boat makers and for refinishing wooden boats with permanent, maintenance-free hull or deck surface. Special Volan AC finish assures complete wetting out, makes a more perfect bond of cloth to wood. Available in special weights and weaves for various marine applications.

industrial fabrics

Standard glass fabrics at low cost to meet your volume requirements. Custom materials developed to meet individual needs. Wide range of weights, widths, weaves. Available plain, finished or impregnated. Ideal for laminates, production parts, structurals, other wet layup operations.

tooling fabrics

Detail, General and Build-Up fabrics at low cost for tooling applications. All are Volan AC finished for easy layup even on complex forms and for excellent wetting out characteristics. A complete range of standard and custom fabrics mass-produced for low cost.

CLAREMONT WASTE MANUFACTURING CO.

The World's Largest Manufacturer of Plastic Fillers

CLAREMONT • NEW HAMPSHIRE

SURFEX-MM®

Precipitated calcium carbonate. Particle size: 1 to 5 microns. Resin coated. Low oil absorption (18-20 cc/100 grams).

PVC Compounds — Low plasticizer absorption. Low viscosity buildup in plastisols. Excellent dispersion, lowers cost.

Polyester Compounds — Improves finish, reduces shrinkage and mixing cycle. Excellent wettability and dispersion.

MULTIFEX-MM®

Ultra-fine precipitated calcium carbonate. Particle size: .04 to .06 micron. Uncoated.

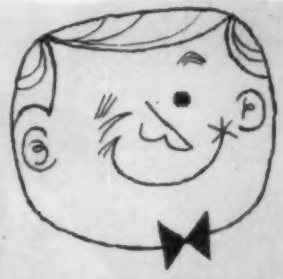
PVC Compounds — Imparts excellent mar resistance, smooth finish and gloss in vinyl floor tile and injection moldings.

Pre-Mix Polyester Compounds — Imparts whiteness and enamel-like finish. Controls viscosity.

SUPER-MULTIFEX®

Particle size extremely fine: .03 micron, very uniform. Coated with two organic surface agents.

PVC Compounds — Imparts excellent mar resistance, gloss, and minimum whitening on flexing.



Plastisols and Organosols — Yields thixotropic effect.

KALITE®

Precipitated calcium carbonate. Particle size about 1 micron. Oil absorption 28-36 cc/100 grams. 1% fatty acid coat.

PVC Compounds — Excellent dispersion and gloss. Improves calendering.

NON-FER-AL®

Precipitated calcium carbonate. Particle size: 5 to 10 microns. Uncoated.

Used in plastisols and organosols to reduce cost and maintain low viscosity and good flow.

SUSPENSO®

Precipitated calcium carbonate. Particle size: 1 to 5 microns. Uncoated. Excellent dispersion.

Polyester Pre-Mix Compounds — With Multifex-MM controls viscosity, imparts whiteness, improves finish, cuts cost and shrinkage. Excellent shelf life.

Polyester Compounds — Disperses readily. Imparts whiteness. Reduces shrinkage and cost. Excellent shelf life.

CIBA

For reds with the stability needed in the finest plastics

Cromophtal Reds

The Cromophtals represent a logical outgrowth of CIBA's traditional research in dyes and synthetic resins. These entirely new and pure organic pigments with high tinctorial strength and soft texture bring together the working advantages of organic pigments with the high fastness properties associated with inorganic pigments. Being disazo pigments of high molecular weight and salt free, the Cromophtals are highly resistant to migration, light, chemicals, heat, organic solvents and plasticizers. To designers and producers of thermoplastics, particularly PVC, this means assurance that ease of application and dependable results go hand in hand when Cromophtals are specified.

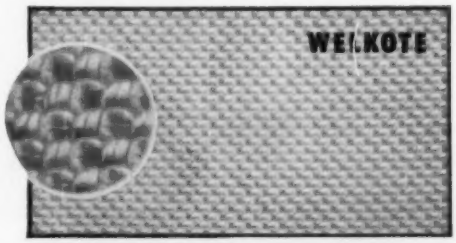
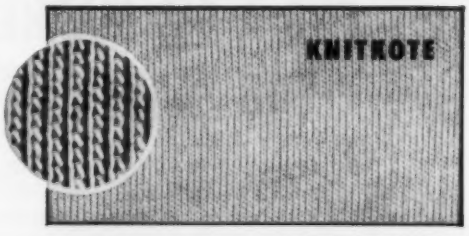
The biggest line of fabrics for COATING

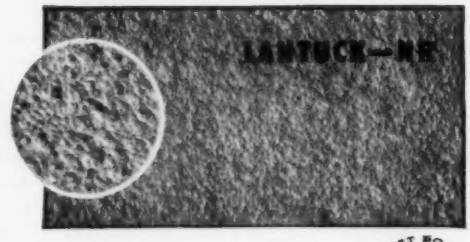


FLEXIBLE AND TOUGH... Wellington Sears broken twills are widely favored by the coating industry, particularly for automobile upholstery, because of their high tear resistance and tensile strength. Their surface smoothness makes a consistently good looking finished product and their flexibility adds good tailoring qualities. Wellington Sears broken twills, soft-filled sheetings and sateens are made up to 72 inches wide in weights of about 6 to 10 ounces per square yard.

VERSATILE BACKING... Uniformly high quality standards of our well-known Columbus sheetings, and also Wellington Sears drills, have established them in a wide variety of coating applications. These fabrics are suited for large-volume use items—wherever high quality, flexibility, easy handling and a minimum of production rejects are essential. Drills are made up to 72 inches wide, 4¼ to 5¼ ounces per square yard. Columbus sheetings are available 40 to 120 inches wide, from 2 to 5 ounces per square yard.



NEW STRENGTH, NEW LIGHTNESS... Welkote is the Wellington Sears filament nylon backing fabric specifically engineered for vinyl and neoprene coating. In truck covers, tents, tarpaulins and other protective coverings, Welkote serves to impart to the coated material superior tear strength, tensile and bursting strength, and flexibility, while giving the finished product remarkable lightness. Available in 36 to 72 inch standard widths (special widths on request), in three basic weights.



SMOOTH, CLEAN SURFACE... Already established in the upholstery field, and developing rapidly in others, this rayon staple fabric furnishes a coating surface that is outstanding for smoothness and cleanliness. In addition, it contributes superior tear strength. This fabric is made in various standard weaves in widths up to 72 inches and weights from about 4 to 10 ounces per square yard. Other Wellington Sears synthetic fabrics include filament rayon; filament and spun nylon, Dacron*; spun dynel and Orlon**.

VITAL ELASTICITY... KnitKote is a cotton knit fabric specifically designed for backings, supplying vital elasticity with perfect shape retention. KnitKote backing gives leathercloth an ease of tailoring unsurpassed by other backing materials, a feature of great importance to the final fabricator. KnitKote is an outstanding base material for coated automotive and furniture upholstery. It is available in the grey or dyed neutrally, 52 to 60 inches wide, 3.60 to 6.70 ounces per square yard.

NEW RESILIENCE... Lantuck-NR non-woven fabric is designed specifically to reinforce vinyl film or coating. A completely random distribution of nylon and rayon fibers is bonded with a special agent, to give vinyl high tear strength; outstanding stretch and recovery; easier, neater tailoring; smooth even surface—no clothiness; good embossing surface; durability and economy; equal tensile strength, tear and stretch characteristics in *all* directions. This and other Lantuck fabrics for coating are made in a variety of weights, fibers and constructions in widths from 37 to 59 inches.

FILLER FOR MOLDING COMPOUNDS

POWMINCO ASBESTOS . . .

. . . An outline of its unusual properties

Powhatan Mining Co. is the exclusive producer of Powminco asbestos fiber, used as a filler and an absorbent and extender in phenolic and polyester resins. It is the only completely fiberized acid resistant asbestos fiber in the United States.

Powminco Asbestos is practically inert. It is not affected by as much as four hours boiling in concentrated hydrochloric acid. This gives it a distinct advantage over ordinary chrysolite fiber when used in molding compounds that require an acid catalyst (phenolics, for example), and in casting resins.

Powminco Asbestos, an anhydrous magnesium silicate, has very little water in its composition. This results in unusually low shrinkage when it is included in plastic compounds used in molding and tooling operations. Other desirable characteristics of Powminco Asbestos are its extremely low magnetic iron, and its very high dielectric strength.

The Powhatan Mining Co. controls the production of Powminco Asbestos from mine to finished fiber, and every processing operation is performed under strict quality controls.

We will gladly supply working samples without charge or obligation. Write to us on your letterhead.

POWHATAN MINING COMPANY

Woodlawn, Baltimore 7 Maryland, U.S.A.

Investigate the packaging field—

IT'S A BIG MARKET FOR PLASTICS!

"Big Market," is right! The men who select the materials used to package the output of America's biggest industries control a market that will hit the 15 billion dollar mark this year.

Typical of the 45 industries that comprise this rich market are companies which manufacture and package foods, cosmetics, chemicals, drugs, candies and tobacco products. In all these highly competitive industries frequent packaging changes are the order of the day. Factors ranging from fascinating sales appeal to plain hard costs influence the men who make the packaging decisions. Consequently, no one type of packaging material (glass, metal, paper or fabric) ever has assurance that it won't be supplanted by another.

And now plastics have entered the arena as directly competitive materials for packaging. In just the last few years they have come to play an increasingly important role—and often at the expense of older, "traditional" materials.

Especially noteworthy is the fact that plastics can be used in the manufacture of almost every basic package type: box, bag, bottle, drum, jar, vial or collapsible tube!

Right now this frontal invasion of the packaging field by alert plastics manufacturers, molders, laminators and fabricators has just begun. And their chief sales tools are the two publications which reach the men who make packaging decisions in all 45 industries—MODERN PACKAGING magazine, issued monthly, and the annual MODERN PACKAGING ENCYCLOPEDIA ISSUE.

Free Details about the Market

Additional data on using these media to help expand your sales to the packaging market are contained in the booklet "The Packaging Field—and how to reach it." Write for your free copy.

Here's how PITTSBURGH FIBER GLASS can help you make better laminated and molded products

1... through top-quality uniformity

Pittsburgh Fiber Glass, produced by the direct melt process under close control, is a top-quality, uniform reinforcement with exceptional strength, dimensional stability and dielectric strength . . . that is fire resistant, heat resistant and odorless.

2... with the right reinforcement for your needs

YARNS—supplied to weavers in any twist or ply in all standard sizes. Reliable uniformity of Pittsburgh Yarns has won its acceptance for use in cloth laminates for military applications.

ROVING—available in a variety of finishes and end counts. Custom wound for your requirements. Static-free Pittsburgh Roving makes pre-form operations easier and faster, produces better quality end products.

CHOPPED STRAND—supplied in lengths ¼" and up. Packaged for convenient handling. High uniform quality reduces percentage of rejects.

3... and technical assistance

You can arrange to have free trials made right in your own plant to show you how Pittsburgh Fiber Glass can help you produce better products. Write or call your nearest Pittsburgh Plate Glass sales office or our main office in Pittsburgh.

Pittsburgh Plate Glass Company, Fiber Glass Division, One Gateway Center, Pittsburgh 22, Pa.

PITTSBURGH FIBER GLASS IS A PRODUCT OF THE FIBER GLASS DIVISION OF PITTSBURGH PLATE GLASS COMPANY

Sales Offices are located in the following cities: Charlotte, Chicago, Cincinnati, Cleveland, Detroit, Houston, Los Angeles, New York, Philadelphia, Pittsburgh and St. Louis

PITTSBURGH PLATE GLASS COMPANY

M & C ALUMINUM SILICATE PIGMENTS (ASP's) . . . *leading fillers for premix and liquid compounds*

ASP fillers are white aluminum silicate crystals of selected particle size that have been process-engineered to remove moisture, sand, mica, water-soluble salts and hard particles. They are essentially non-reactive and insoluble in common solvents. These particles have a thin, flat hexagonal shape as illustrated in this electron photomicrograph (35,000X).

Examine the following characteristics of M & C ASP fillers and you'll see why they are being used by a rapidly growing number of formulators, processors, and molders. ASP's offer you molding ease, excellent finishes and improved properties—often at a substantial cost savings. And Minerals & Chemicals has extensive research facilities and qualified personnel to help you with your specific problems.

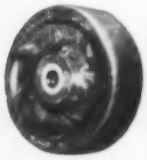
Uniformity of Filler Dispersion—ASP's mix easily, stay in suspension, and maintain a homogenous mixture during molding. In premix compounds, they wet out and disperse readily.

Ideal Viscosity and Thixotropic Characteristics—Certain grades of ASP's have low viscosity and thixotropy that permit fast press closure, rapid mold fill-out, and less tendency of the mix to escape after die closure.

Long Pot Life—Because of their natural low reactivity, ASP's have excellent pot life characteristics.

Outstanding Electrical and Physical Properties—ASP's offer a desirable combination of electrical properties including high dielectric strength, high arc resistance and a low power factor. Reasonable quantities of ASP fillers can be used without serious loss in flexural, tensile, compression and impact strengths. They have excellent water and chemical resisting characteristics, and their flat shape and freedom from foreign particles make them non-abrasive.

Positive Shrinkage Control—ASP's aid in controlling uneven cooling and shrinking that cause cracking and low physicals because they prevent excessively high exothermic peaks. The rapid absorption of exothermic heat by ASP's produces a more even internal cooling rate.



Ease of Molding—ASP's assure molding ease because of their optimum combination of certain properties such as low viscosity, thixotropy, and natural lubricity resulting from their plate-like shape.

Superior Surface Characteristics—ASP's produce smooth surfaces of high gloss because of their refractive index and flat, plate-like particle shape. High opacity or some translucency can be obtained depending on the type of ASP used. The non-reactive nature of ASP's aids in obtaining good adhesion of protective or decorative coatings.

Wide Range of Particle Size Grades—ASP's have a particle size range from 0.55 microns to 4.8 microns with intermediate sizes.

Jeep Hard-Top of ASP filled reinforced plastic has durability yet stylish surface.

Caster wheel with ASP filler has impact strength double the industry standard.

ASP filled airline tray features long life, smooth surface.

Fertilizer hopper made with ASP's at high filler loading is dense, strong, translucent.

FOR ADDITIONAL DATA ON ASP's write for the just-published 4-page Technical Information No. 255, "Minerals & Chemicals Aluminum Silicate Pigments (ASP's) As Fillers in Plastics."

FERRO FIBER GLASS

reinforcements for plastics

FIBER GLASS REINFORCEMENTS IN EVERY FORM...FOR EVERY PURPOSE

FERRO UNIFORMAT®

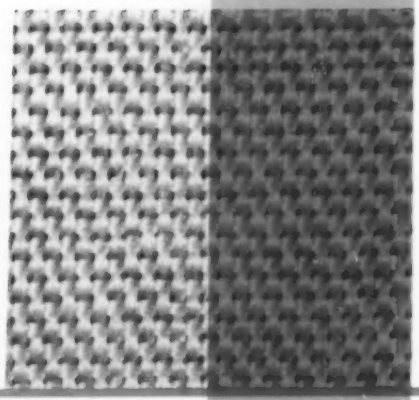
FIBER GLASS REINFORCING MAT

Ferro *Uniformat* Reinforcing Mat is made by cutting 14,000 yards per pound, continuous strands, into 2″ lengths and depositing them in a random pattern in the form of a continuous length of firm, bonded mat.

The unique method of producing *Uniformat* results in a mat of uniform weight and texture having equal reinforcing strength in all directions. The greater uniformity of *Uniformat* insures greater overall product strength—eliminates weak areas caused by variations in mat weight and pattern.

Mat integrity is sufficiently high to allow the material to be handled, tailored and laminated without tearing.

Standard roll widths are 50 and 60 inches. These can be varied to any desired width between 25″ and 61″.



Continuous quality control at Ferro assures that every roll of Ferro *Uniformat* conforms to the customer's "specs"—and to Ferro's high standards for uniformity.

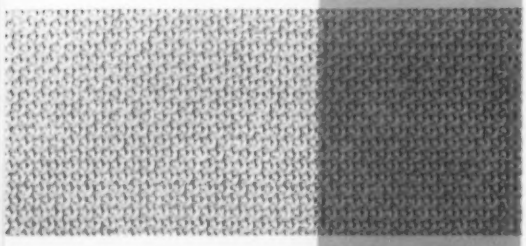
FERRO UNIROVE

FERRO FIBER GLASS

reinforcements for plastics

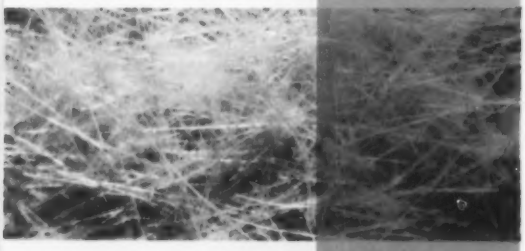


FERRO UNIROVE®

WOVEN ROVING

Particularly useful in plastic reinforcement of heavy industrial products because of its high strength in relation to reinforcement cost.

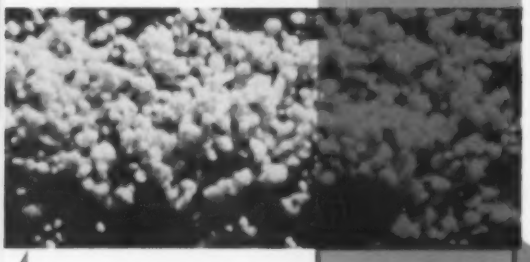
Write for samples, specifications and prices.



FERRO UNIFAB®

REINFORCING FABRICS

Ferro *Unifab* Industrial Glass Fabrics are made exclusively for the reinforcement of plastics.

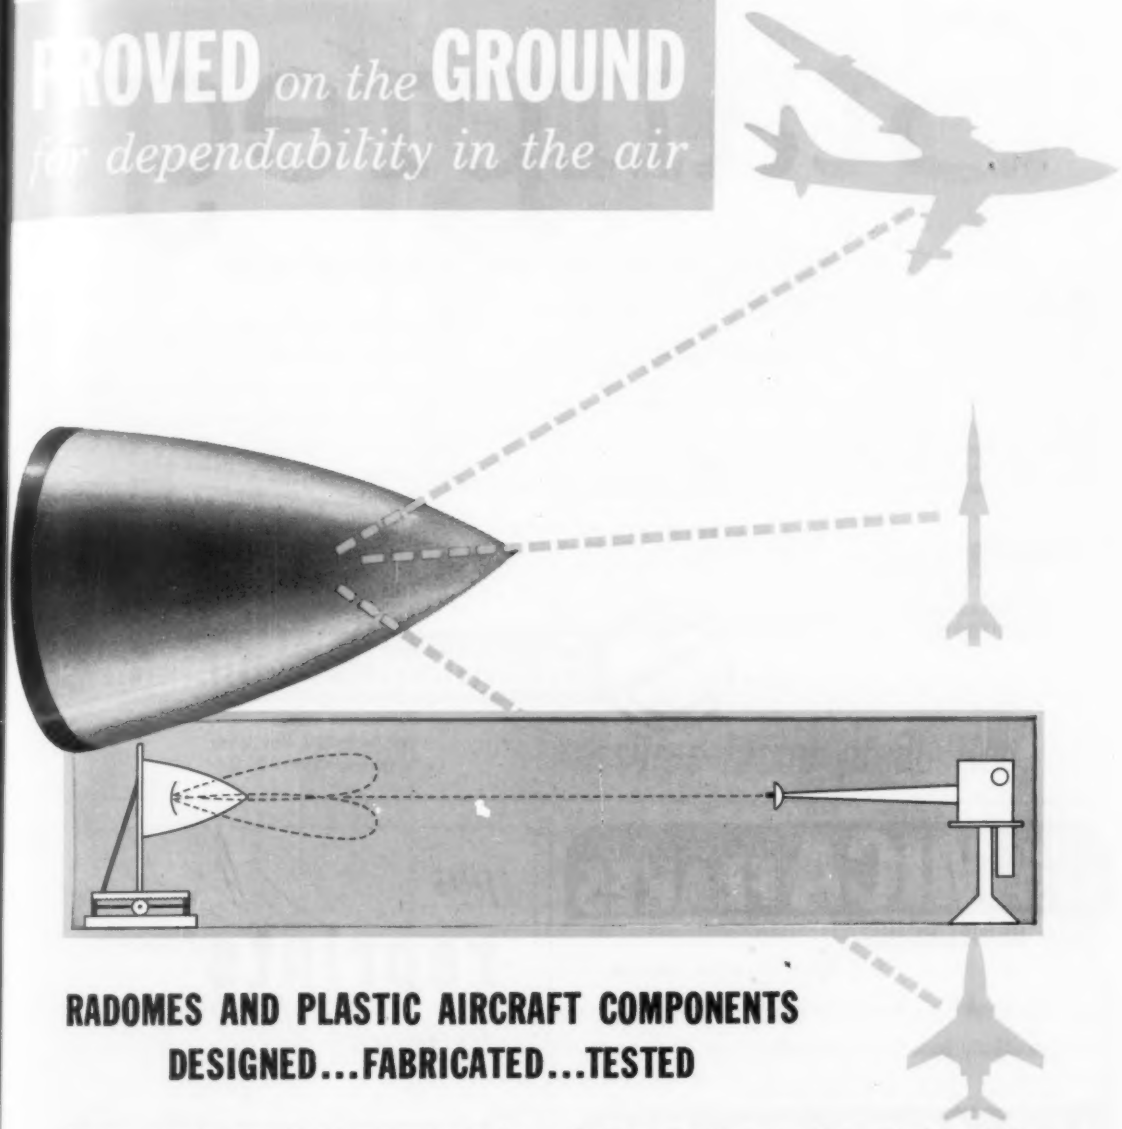


Produced to Ferro's high standards of quality, *Unifab* Fabrics are consistently *uniform* in weight, thickness and weave.

Write for samples, specifications and prices.

FERRO CHOPPED STRANDS

Ferro Chopped Strands are made of the same fiber as in *Uniformat*, cut in lengths of ¼", ½", ¾", 1", 1¼", 1½", 1¾" and 2". Primary uses are in premix formulations, casting resins and certain pre-form applications.



FERRO MILLED FIBERS

Made by milling 14,000 yards per pound continuous strands and reducing them to the form of short lengths of filaments. Supplied in ½", ⅛", ⅛" and ¼" screen sizes. Use Ferro Milled Fibers to help prevent crazing in casting and potting resins, for control of viscosity of liquid resins, for dielectric improvement.

RADOMES AND PLASTIC AIRCRAFT COMPONENTS DESIGNED...FABRICATED...TESTED

Electronic testing provides for automatic simultaneous recording of boresight error, crosstalk and power transmission. Power sources and R. F. components are available throughout the frequency range of 2 to 35 kmc. plus the U.H.F. range.

In the area of physical testing, Brunswick offers stress fixtures, an environmental chamber and an altitude cycling chamber.

These are just a part of Brunswick's complete facilities covering every phase of radome design, development, fabrication and testing. And behind these facilities lies a continuous research program.

Whatever your problem involving plastic radomes, or other aircraft components of reinforced plastics, metal honeycomb or conventional metal construction, discuss it with Brunswick today. Write: The Brunswick-Balke-Collender Company, 623 South Wabash Avenue, Chicago 5, Illinois.

BRUNSWICK

Stanpreg

pre-impregnated materials

POLYESTER glass cloths, woven rovings and mats combine maximum strengths with flame resistance for commercial and military applications.

EPOXY glass cloths and papers for optimum electrical and physical characteristics. Flame resistant and high temperature resistant types available.

PHENOLIC glass cloths and mats, papers and cotton cloths for high structural and high temperature resistant qualities.

SILICONE glass cloths for maximum strengths at exceptionally high temperatures.

XXXP – Cold Punch Phenolic paper for excellent electrical characteristics combined with outstanding cold punching properties in laminates up to 1/8" thick.

For *your* Reinforced Plastic requirements.

Uniformly resin impregnated and catalized Stanpreg materials are instrumental in achieving maximum production rates while cutting rejects to a minimum. Optimum properties of Stanpreg products are designed to meet a wide range of government and industrial specifications.

reprints

to work!

Reprints of articles, features and news items that appear in Modern Plastics are often surprisingly inexpensive when ordered in quantity. Many companies make it a practice to have stories which have a hearing on their business reprinted for distribution to their own personnel, customers, prospects, stockholders or to other interested groups.

Whenever you see editorial matter of this type in Modern Plastics magazine or the Encyclopedia issue which you can use in reprint form, in quantities of 100 copies or more, write and quotations will be furnished promptly.

New low-cost SUNFORM® Reinforced Plastics For Low Pressure Laminating to meet military specifications— assures faster production

Electro-Tech now offers new polyester resin formulations, as well as other pre-impregnated materials using epoxy, phenolic, melamine and silicone resin systems, and custom impregnations for low-pressure laminating—while maintaining the same high specifications.

SUNFORM saves both time and money. Controlled resin and catalyst impregnation assures fewer rejects and void-free laminates with multiple layers for such applications as, housings, fairings, ducts, sonar domes, radomes, doors, etc.

SUNFORM laminates have high tensile and flexural strengths, and exceptional stability even under extremes of temperature and humidity. Dielectric strength is high, loss factor low and moisture resistance excellent. A selection of colors is available on large orders.

Do you know all the latest ways to cut your packaging costs?

Are you familiar with new developments in package design that stimulate retail sales?

Are you sure you're using the best kind of package to protect your product from damage?

If you had to answer "No" to any one of these questions, it's likely that you're unnecessarily losing money every business day.

Fortunately there's an easy way out: MODERN PACKAGING magazine! It's the world's most authoritative publication devoted exclusively to packaging problems and their solutions. It analyzes all of the newest developments in packaging—materials, machinery, design and production. It reports each of the latest ways to merchandise packaged products of all types, from frozen foods to monkey wrenches.

The cost of an annual thirteen-issue subscription—including the giant annual Encyclopedia Issue—is only $7.00 in the U.S., its possessions and Canada; $20 elsewhere. You can begin yours today simply by writing us on your business letterhead. We'll bill you later.

FLOCK

FILLER:

"Filfloc" Cotton Flock

Reinforcing flock for inclusion in plastic molding compounds. Available in a range of cut and deniers engineered by our 32 years experience to suit your needs with optimum effectiveness.

SURFACE-COATING:

"Raycote" Rayon Flock

Precision-cut
1 mm velvet finish
½ mm suede finish
Raycote, we believe, can be applied so as to produce the richest effect of any flock on the market. Quality raw material and exceptional precision of cut make it superior.

"Kingkote" Cotton Flock

Random-cut within strict length limits. Produces a suede effect of richness and durability.

Surface Coating of Vacuum-formed Plastics

Containers vacuum formed from plastic film can be coated after forming and can also be pre-flocked before forming. Request details.

WRITE

for latest literature and samples. We make a complete line of natural and synthetic flocks in all colors. 32 years of know-how at your service.

PAWTUCKET, RHODE ISLAND

Solve your abrasion, corrosion and surfacing problems with Troytuf reinforcing blankets

Troytuf reinforcing materials are made of mechanically interlocked synthetic fibers—no binders or adhesives are used. The result is a high strength, light weight, easily handled reinforcing laminate.

Synthetics used are Dacron* polyester and Orlon* acrylic fibers. Troytuf made with Dacron is a general purpose blanket, suitable for a wide variety of applications. Troytuf made with Orlon is especially fitted for jobs involving weather exposure, and for finished laminates requiring paint.

Troytuf blankets give you

- **high abrasion resistance**
- **excellent electrical properties**
- **uniform fiber loading, without resin rich corners**
- **high resistance to mineral acids**
- **elimination of pre-forming**
- **safe material for food containers and utensils, because of the absence of sharp fragments**
- **smooth, attractive surface finish**
- **good formability after curing**
- **low moisture absorption**
- **no shelf life problem—because no binders or adhesives are used**

Troytuf blankets are especially suitable for

molding deep-draw pieces—because the loose blanket readily conforms to irregular shapes

printed circuitry; radomes, other electrical and electronic applications—because of Troytuf's excellent dielectric and electronic transmission properties

general reinforcing applications—because of Troytuf's light weight and great strength

* * *

Why not get the full story. Write for your free copy of the *Troytuf Technical Data Booklet.* It gives extensive information about properties and applications, and includes a price list.

Laminates and Laminating

By definition, laminated plastics "consist of superimposed layers of a synthetic resin-impregnated or -coated filler which have been bonded together, usually by means of heat and pressure, to form a single piece."

Laminates are generally divided into groups according to the pressures required to cure the resin or binder. The group of laminates made with resins requiring curing pressures over 1000 p.s.i. are generally termed "high-pressure laminates." Further subdivision of this group is made on the basis of filler, resin type, or end-use (e.g., phenolic-glass, silicone laminate, industrial laminate, decorative laminate, etc.). Most of these high-pressure laminates are used in such primary forms as sheets, rods, tubes, and cross-sections. More recently, molded forms have come into use.

The so-called "low-pressure laminates" were originally intended to cover those forms molded at pressures under 400 p.s.i. More recently, in the interests of production economies, higher pressures have started to be applied to the manufacture of these materials. The term "reinforced plastics" is generally used to describe such materials, although actually the term can be applied to any resin reinforced with any fiber, e.g., even fibrous glass-reinforced styrene.

HIGH-PRESSURE LAMINATES: GENERAL BACKGROUND

BY J. R. DUDLEY* and GLEN W. NEELY*

The technology involved in the manufacture and processing of high-pressure laminates is complex and requires extensive control facilities and well-trained technicians. Wide variations in properties are possible, and it is recommended that the design and processing engineer contemplating the use of laminates seek assistance from technical service representatives of those companies engaged in the production of laminates.

Materials: The selection of resins and reinforcements for the laminate is determined by the required characteristics sought in the end-product—and a wide variety of materials are available to meet these requirements. The most commonly used resins for high-pressure laminates are the phenolics, melamines, silicones, epoxies, and polyesters; most commonly used reinforcements are woven and nonwoven cotton, glass, asbestos, or synthetic fibers and kraft, alpha, and rag papers.

Saturation: Initial step in the manufacture of a high-pressure laminate is passing the reinforcing material through a bath of resin for impregnation. The amount of resin and degree of penetration will depend on the viscosity of the resin, temperatures used, time of immersion, permeability of the reinforcement, and the like. The setting of metering rolls, if used, can also have an important effect on the end-product. Squeeze rolls or doctor blades, for example, applied to the impregnated material after it has passed through the bath, can be adjusted to control the amount of resin remaining in and on the web. Roll coaters have also been used to meter resin onto the web.

After saturation, the material is conveyed through a horizontal or vertical drying chamber to reduce volatile content to the desired amount.

Sheets: In the manufacture of high-pressure laminate sheets, the saturated material is first cut to the required size. Sheets are then laid one on top of the other until a predetermined weight is reached. Thus, the laminator can control the thickness of the finished laminate after consolidating under heat and pressure.

By varying the type of materials

* Director of Research and Development and Sales Engineer, respectively, The Richardson Co., 2747 Lake St., Melrose Park, Ill.

Recent Developments and References were prepared by the editors.

Fibrous glass-reinforced polyester (*Hetron*) panels (*Fire-Snuf*, Resolite Corp.) have been approved by Factory Mutual, insurer of industrial buildings, for use in industrial construction. Tests showed that these panels would in no way contribute to flame spread throughout an industrial plant in the event of fire.

Outstanding electrical properties from power through radar frequencies and continuous heat resistance up to 250°C. are exhibited by a new Teflon (Du Pont) bonded glass cloth laminate (*Dilecto Grades GB-112T, GB-116T,* and *GB-12T,* Continental-Diamond Fibre Corp.). The laminate is recommended for microwave applications in both plain and copper foil-clad grades because of its extremely low dissipation factor.

Flame-retardant sheets and tubes in both paper-base and epoxy-glass cloth and polyester-glass mat sheets (Continental-Diamond Fibre Corp.) are available for panels, sub-panels, terminal strips, guards, spacers, television fly-back transformer panels, switchgear, and many other electronic equipment applications where flame-retardant properties are required along with good electrical and mechanical characteristics.

A flexible glass mat laminate (*Glastic Grade FM,* The Glastic Corp.) available in thicknesses of 1/32, 3/64, and 1/16 in. has formability and heat resistance not usually found in polyester laminates. In 1/32-in. thickness, this material will not lose dielectric strength after wrapping on a 3-in. diameter mandrel, nor after continuous exposure to 130°C.

A new cold-punching laminate (*Insurok XT-896,* The Richardson Co.) has low moisture absorption, low dielectric loss at high frequencies, and good insulation resistance. It punches clean at room temperature. In copper-clad form, the material has high bond strength and good blister resistance. Applications include mechanical assemblies and printed circuitry.

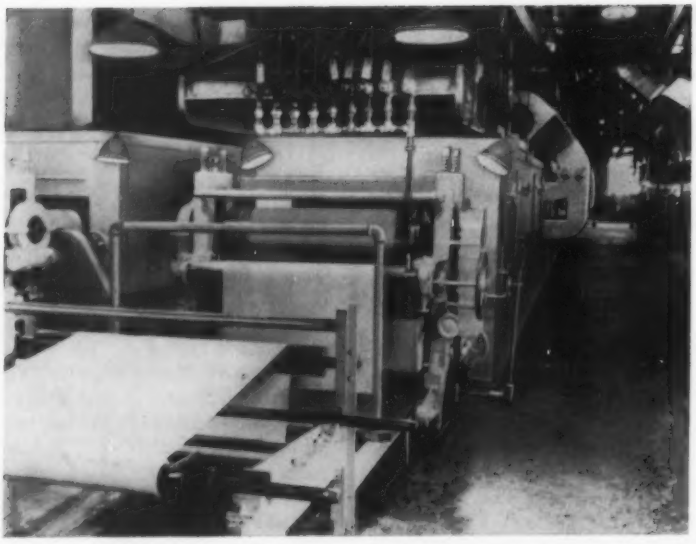
A paper-base phenolic laminate (*P-25,* Synthane Corp.) with good electrical properties and cold punching and cold shearing characteristics is recommended for copper-clad laminates used in printed circuitry.

An electrical grade phenolic laminate (*Phenolite E-2040,* National Vulcanized Fibre Co.) developed for radio and TV applications has good electrical properties and extremely low cold flow.

A line of polyester resin-glass mat laminates (*GP-9100, GP-9104,* and *GP-9202,* National Vulcanized Fibre Co.) have properties similar to the reinforced plastics used in sports car bodies, and offer dimensional stability and exceptionally high impact strength, combined with good arc resistance.

A new laminate for engraving (*Gravalum,* Hermes Plastics) has an ebony black phenolic center core bonded between two exterior layers of satin-finish aluminum. Engraving through the top layer exposes contrasting black lettering, eliminating the filling of engraving with paint. The laminate is masked on both sides for protection, and engraving is done through the masking material to avoid scratches.

An epoxy-impregnated translucent paper laminate (*Nelco-130,* New England Laminates Co.) is said to cold-punch to 1/16 in. without cracking, to absorb only 0.25% water after 24-hr. immersion, to be free of volatiles, and to have good dimensional stability.



A fire-resistant, glass fabric-reinforced, polyester resin laminate (*Conolite A20SG1Y,* Continental Can Co., Inc.) was developed to replace aluminum and dope-coated Irish linen as wing and fuselage covering-material for small aircraft and has been approved by the C.A.A. for this application. It is produced by a unique, continuous process and therefore is available in rolls up to 150 ft. and cut-to-size sheets with a maximum width of 36 inches.

Fibrous glass-reinforced plastics panels (*Security Junior,* Resolite Corp.), featuring embedded aluminum or steel diamond mesh, offer unusual architectural design possibilities, as well as semi-transparent protection against flying particles and liquid spray. The panels have high impact resistance because of the metal mesh reinforcement. They have light transmission values ranging from 71% (clear) to 15% (coral), the average being 50 percent.

Flat translucent sheets of reinforced plastics (*Glazor,* Strick Plastics Corp.) press molded from 3-oz. glass mat and polyester resin are available in sizes ranging from standard sash to 48 by 96 inches. The manufacturer states that this material will support 100 lb./sq. ft. on a 4-ft. span and that it can be made flame-resistant by the use of self-extinguishing resin. It is suggested for use in skylights, greenhouses, sidewalls, shower stalls, etc. This company also makes a corrugated sheet reinforced with 2-oz. mat (*Daycor*).

An adhesive (*Adhesive No. 156-2,* Flex Craft Industries) for glass-reinforced polyester sheeting can be used to bind the reinforced sheet to itself or to paper, metal, wood, fabrics, or to other plastics. Applied by conventional roller coater, spraying, or brush, the adhesive is of a medium viscosity and dries quickly.

Decorative fibrous glass-reinforced polyester laminates (*Tropiglas,* Russell Reinforced Plastics Corp.) now supplement a line of structural-grade polyester-glass laminates. The decorative laminates are available in single-wall and sandwich-type construction and are listed under the trade names of Cathedral Tropiglas, Woodcurl Tropiglas, Chromacel Tropiglas, and Mosaic Tropiglas.

Coating machine for paper used in laminates is designed to provide close control over amount of resin with which paper is impregnated. (Photo, J. O. Ross)

used in the lay-up, a wide range of sheets with varying characteristics can be turned out. Sheets can be made up entirely of one type of saturated material or of the same material with varying degrees of saturation or even of different combinations of materials. For example, a sheet may be composed of kraft paper of one saturation for the core and a kraft paper with a different saturation for the surface sheets, or it may have a kraft paper core and a fabric surface sheet, and so on.

Pressing of the sheets is done between heated platens (generally in a vertical-acting, multi-opening unit) under carefully controlled temperature, pressure, and time cycles.

Rolled tubes: Rolled tubes are manufactured by convolutely winding the saturated material around a polished mandrel and then cradling the material between heated rollers and a pressure roll. The saturated material should be under tension.

After a sufficient amount of material is wound on the mandrel, the assembly is cured in an oven to complete consolidation. The mandrel is then withdrawn and the tube is centerless ground or machined to desired diameter.

Molded tubes: Molded tubes are produced by convolutely winding saturated material around a mandrel and molding the combination in a heated, split-type mold. The mold is designed to cut or pinch off the excess material that protrudes along the side closures as the two members are brought together under pressure to size the outside diameter. The mandrel which sizes the inside diameter cannot be anchored. Therefore, the wall thickness is subject to more variation than in the case of rolled tubes. The tube is then centerless ground to desired size.

Since molded tubes are cured under heat and pressure, their characteristic values approach or are equal to laminated sheets. Molded tubes of relatively thin walls will have less strength on each side where the saturated material is pinched off as the mold closes.

Rods: Rods are produced by molding or by centerless grinding square strips cut from sheet materials. The molding process is identical to the molding of tubes except that a mandrel of minimum size is used for winding the material and is removed before placing the wound preform into the mold. The molded rod is then centerless ground to desired size.

Molded laminates: Parts produced by molding laminated materials are beginning to receive more consideration by design engineers. By proper saturation, preforming, and tailoring of the reinforcing materials, parts can be produced having strength characteristics many times greater than conventional molding compounds. By proper design and positioning of the saturated material in the mold, parts can also be produced having greater strength than identical parts fabricated from flat laminates.

One technique for molding laminates is to place small squares of impregnated filler materials into a mold of the required design and then curing by the application of heat and pressure. Cut strips of filler materials placed in layers in the mold can also be used.

Applications: In addition to those laminates produced for specific applications, a wide range of standard laminates are available to the design engineer (see Table I, p. 509).

The laminates have much to offer. Their high strength (on the basis of strength-weight ratio, laminated materials are among the strongest known) makes them suitable for many aircraft, structural, and other key industrial applications. Strength, moisture resistance, and good electrical properties make them a volume material in the electrical industry. Gears machined from laminates also find volume markets by virtue of their high strength, good wearing qualities, and ease of machinability. Printed circuits based on laminate bases hold great interest in present-day electronics design (see p. 511). The use of silicones and high-temperature phenolics has resulted in laminates that can operate at higher levels of temperature than were previously possible. Epoxy resins have contributed to certain improvements in electrical characteristic values, and recent resin combinations have improved strength, machinability, and stability of mechanical grades. With additions of graphite and molybdenum disulfide, separately or in combination, the coefficient of friction has been reduced for bearing applications. The use of polyester or similar resins as binders for such inorganic reinforcements as glass or asbestos fibers has improved the chemical

TABLE I: Properties and applications of industrial NEMA grade laminates[1]

NEMA grade	Typical properties	Typical applications
X	Paper phenolic. General-purpose grade, high strength, low cost.	Panels, contactors, terminal blocks, insulating washers.
P	Paper phenolic. Punch grade, not as strong as X. Low cost.	Spacers, switch links, and miscellaneous small punched parts.
PC	Paper phenolic. Similar to P but recommended for punching at ambient temperatures. Lower strength and greater cold flow than P.	Same applications as P except for limitation of strength and cold flow.
XX	Paper phenolic with better electrical properties than X or P.	Miscellaneous parts for communication equipment, switchboard panels, and exposed parts.
XXP	Paper phenolic better than XX in electrical properties and humidity resistance. Can be punched hot. High strength.	Relays, vibrators, tube sockets, communication equipment.
XXX	Paper phenolic. Suitable for high-frequency, low-loss application in high humidity.	Radio, radar, and television, high-voltage parts. Printed circuits.
XXXP	Best paper phenolic electrical grade. Highest dielectric strength and lowest dissipation factor. Can be punched hot (some manufacturers now offer a special XXXP grade that can be punched cold).	Punched parts for critical electrical application. High-voltage and high-frequency uses. Printed circuits.
ES-1	Paper base engraving stock. Core and face of contrasting color.	For engraved nameplates.
ES-2	Similar to ES-1 except for color.	For engraved nameplates.
ES-3	Similar to ES-1 except for color.	For engraved nameplates.
C	Cotton fabric phenolic. Cloth heavier than 4 oz./sq. yd. Not recommended for electrical uses. High impact strength.	Mechanical application gears and bearings, rayon spinning buckets, miscellaneous disks, pistons, and rings for pumps and valves.
CE	Similar to C but with controlled electrical properties. Better in humidity; not for high-voltage primary insulation. Better for machining than grade C.	Bus bars, panel boards, slot wedges. Many applications same as C.
L	Cotton phenolic with fabric less than 4 oz./sq. yd. Called linen grade by the trade. Better machining than C and CE. Lower impact strength than C. Not an electrical grade.	Mechanical parts for pumps, valves, clutches, etc. Small gears and bearings.
LE	Similar to L but with better moisture resistance and controlled electrical properties. Not as good electrically as paper-base laminates. Not for high-voltage primary insulation.	Small parts, both mechanical and electrical, that require good punching and machining qualities.
MC	Melamine laminate reinforced with cloth similar to C grade. Excellent arc resistance and better resistance to alkali than phenolic laminates. Between C and CE in moisture absorption.	Electrical uses requiring arc resistance. High-voltage switchgear and terminals.
A	Asbestos paper phenolic. Better heat and flame resistance than cellulose paper phenolic. Not recommended for primary insulation at over 250 v. Difficult to machine. Very low moisture absorption. Very low cold flow.	Low-voltage, electrical application in electric welders, traction motors, etc.
AA	Asbestos cloth phenolic. Properties similar to A but better strength.	Often molded into shapes for collector rings, commutator parts, and armature wedges.
G-2	Staple fibrous glass cloth, phenolic binder. Excellent electrical properties under high humidity. Very low dielectric losses.	Electronic equipment.
G-3	Continuous filament glass cloth-phenolic laminate. High strength except bond strength is poor. Good dimensional stability at elevated temperatures.	Electronic equipment.
G-5	Continuous filament glass cloth-melamine laminate. Second only to silicone laminates in arc and heat resistance. Best in flame resistance.	Electronic equipment. Printed circuits for high voltage.
G-6	Stable fibrous glass cloth with silicone resin binder. Superior dielectric loss and insulation resistance properties. Good heat and arc resistance. Meets AIEE requirements for Class H insulation.	Electronic application requiring Class H material or very low dielectric loss.
G-7	Continuous filament glass cloth with silicone binder. Similar to G-6 except flexural strength is higher and bonding strength is lower.	Similar to G-6.
G-10	Continuous filament glass cloth with epoxy resin binder. Extremely high flexural impact and bonding strength. Superior electrical qualities in humidity.	High-frequency electronic parts. Printed circuits for military applications.
N-1	Nylon cloth base with phenolic binder. Excellent electrical properties in high humidity. Good impact strength, low modulus. Easy to punch. Subject to flow at elevated temperatures.	Specified by MIL-P-15047 for certain military applications.
CF	Cloth phenolic similar to C grade except that it can be formed into simple shapes when heated. Called postforming grade.	Used to form angles, channels, and other simple shapes. Not recommended for high-voltage electrical applications.
GPO-1	Random fibrous glass mat bonded with polyester resin. A low-pressure laminate. Can be made flame retardant. Good arc and heat resistance.	Mechanical and electrical uses. Excellent for structural applications requiring an insulating material.

To choose a laminate for a particular application, reference should be made to the standards publication of the National Electrical Manufacturers Association, 155 E. 44 St., New York 17, N. Y., or to the catalogue information supplied by one of its members. In most cases, catalogue information is to be preferred because manufacturers often have more than one grade corresponding to a given NEMA classification.

[1] Prepared by Laminated and Insulating Products Dept., General Electric Co.

resistance of laminates. There has also been considerable improvement in the decorative laminates field, resulting in more faithful reproduction of wood grains and colors and greater mar resistance. A more detailed discussion of these various types of special-grade plastics is offered in the article below.

HIGH-PRESSURE LAMINATES: SPECIAL GRADES

BY F. WILLIAM JAHNS, JR.*

Most of the specialized laminates involve the use of the newer resins, e.g., silicones, epoxies, etc., or combinations of several different types of core or facing materials. It is these that will be discussed in this chapter, together with some of the more important specialized markets such as missiles and printed circuits.

Combination laminates

In many cases, it is desirable to use combination laminates in which the facing is different from the core of the build-up. Typical examples are: a phenolic core with a vulcanized fibre facing designed to impart arc resistance to the facing; arc-resistant fuse tubing with a vulcanized fibre core to provide arc quenching and with a paper or epoxy-glass overwrap to offer high mechanical strength; various types of metal bars with a paper-base phenolic laminate or other covering to provide insulation; and various combinations of phenolic laminate cores surfaced with natural or synthetic rubber, and, in some instances, with cork to act as a seal on the tops of electrolytic condensers.

For many years, metal tubes have been covered with phenolic laminates for use as conveyor rolls in metal processing operations. It is also possible to use conductive inserts, such as aluminum or copper foils, in the make-up of paper-base phenolic or other types of laminates. In this instance, the conductive inserts provide a means of ground connection and also increase the corona resistance due to better distribution of the electrical stress.

Various types of synthetic fiber surfaces on a core of glass base polyester laminates are used in increasing the chemical resistance and providing lower abrasive qualities than are exhibited by the conventional glass-polyester laminate without such a synthetic fiber covering.

Established applications for a metal tube with a fabric-base phenolic covering exist in aircraft landing gear equipment and hydraulic pistons.

With the advent of cementable Teflon[1], it is now entirely feasible to apply a Teflon surface, either in the unsupported or glass-supported form, to such materials as paper-base phenolic laminates or glass-base epoxy laminates for electrical insulating or low coefficient of friction properties.

Glass-Teflon laminates

Glass-base Teflon laminates, which have outstanding electrical properties, have found market outlets in critical military items and, in some instances, applications in areas where corrosive atmospheres would deteriorate other types of laminates. Among its advantages are outstanding heat resistance and the retention of low-loss electrical properties over the complete frequency range usually encountered. The importance of this glass-base Teflon laminate for military use is indicated by the recent issuance of a military specification covering this product.

Epoxy laminates

Some of the more important properties responsible for the increasing acceptance of epoxy laminates in many fields are: low dimensional change, fungus resistance, minimum gassing, high mechanical strength, Class B temperature use (325 to 350° F.), superior bond strength, low water absorption, and compatibility with epoxy potting compounds used for encapsulation.

In addition to the above properties, glass-base epoxy tubes, both plain and when combined with a vulcanized fibre liner, have exceptionally high bursting strength. This feature has caught the attention of many manufac-

turers, especially those engaged in the production of high-voltage fuses.

Silicone laminates

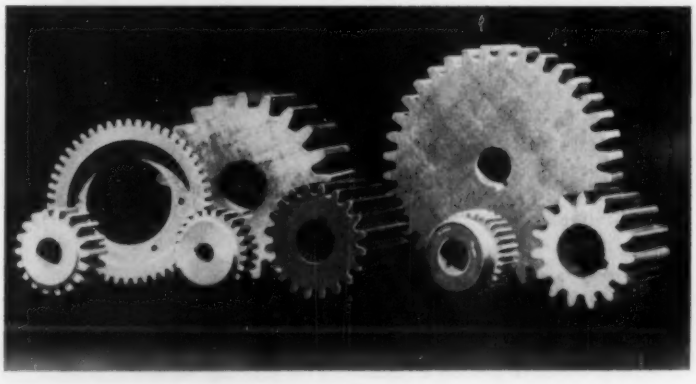
Glass-base silicone laminates are now widely used as an insulating medium in electric motors, generators, and transformers. These laminates have been responsible for a substantial increase in power output for a given size unit of electrical power equipment. They combine better heat resistance, as compared to phenolic grades, plus arc resistance, low moisture absorption, and good electrical properties which are retained under humid conditions and after prolonged exposure to high temperatures.

Some of the better-known applications of silicone laminates are in deicing units and radar equipment.

Laminates in missiles

Reliability is a key reason behind the use of laminates in missile applications. As an illustration, it is pointed out that in guided missiles using only 100 components, each of these can fail only once in 1000 times if the missile is to have a 90% reliability. In actual practice, however, missiles use many more than 100 components, thereby making reliability even more important.

The usual applications of laminates in missiles include fins and guidance and control systems. Appreciable quantities of glass-base polyester, epoxy, silicone, Teflon, and phenolic laminates are used in these applications. In missile components where higher reliability and superior performance are of paramount concern, the relatively high cost is warranted.



The guidance systems of missiles usually represent about 50% of the entire cost of the missile, although those systems constitute only 5 to 10% of the total weight. The use of glass-base epoxy copper-clad laminates in printed circuits designed for missiles contributes to miniaturization.

Printed circuits

Manufacture: There are a number of methods by which printed circuits can be produced. Metal foil may be applied to either one or both surfaces of a base laminate. When copper foil is used, either electrolytic or rolled copper may be applied.

A common method is to apply

Gears, characterized by high mechanical strength, long wear, and silent action, are cut from a phenolic-canvas base stock. (Photo, Continental-Diamond)

a thin sheet of metal (usually copper) to one surface of a base laminate. For most industrial uses, a NEMA XXXP grade (paper-base phenolic type) is employed as the base. For certain applications, a NEMA G-10 (glass-fabric-base epoxy) grade is desirable. Many other base laminates are also used.

The desired pattern is then applied to the copper surface, usually by printing or silk screening, using an acid resist. After further processing, the metal-clad laminate is placed into an etching solution to remove that portion of the copper which has not been given an acid resist treatment. The acid resist is then removed by solvents.

The prepared board is completed by punching holes for insertion of the leads of component parts such as condensers, resistors, tubes, transistors, and sockets to the side of the panel opposite the printed circuit pattern. For large-quantity runs, the components are usually inserted by automation processes.

As the final step, the side of the panel on which the circuit has been printed is subjected to a solder bath.

Many copper-clad laminates may be cold punched. To enable a visual check on register, these are available with translucent properties.

When some severe service conditions are involved, printed circuit boards are plated with metals, such as gold, nickel, rhodium, lead-tin, chrome, and tin. In processing printed circuits, modern equipment, such as Wiedemann "printed circuit" turret punch presses and Zagar multiple drilling heads, is used.

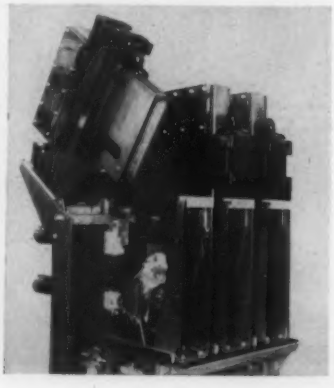
There are a number of printing techniques used, and each differs significantly in its adaptability and usefulness for automation processes.

Advantages and uses: Printed circuits in various forms are going into an ever-increasing number of applications.

Some of the more important advantages responsible for their wide acceptance are: 1) unit construction of component parts and assemblies; 2) greater simplicity of wiring; 3) each printed circuit

Paper used in manufacture of decorative laminate is coated with melamine resin. As paper slides out of trough (above), it is dried in vertical tower. (Photo, American Cyanamid)

is identical, with the result that there are no wiring errors; 4) faster production; 5) less floor space is required for manufacturing areas; 6) lower manufacturing costs are possible due to faster production; 7) lower rejects; 8) savings in material costs and overhead; and 9) component assemblies, subassemblies, or individual terminal boards may be solder dipped, which permits the soldering of many joints in one operation.



Some of the more important applications of printed circuits are: hearing aids, small portable receivers, telephone terminal boards, radio and television receivers, missiles, ground missile controls, analog and digital computers, radar equipment, telemetering equipment, switches and code disks, tape recorders and dictaphones, microphones (small lipstick type), business machines, and toll road counters.

There is an increasing interest in the flexible type of printed circuits. These flexible circuits are usually manufactured from thin sheets of such base materials as copper-clad glass-base epoxy laminates and copper-clad glass-base Teflon laminates. The thicknesses normally range from 0.010 to 0.015 inch.

One special type of copper-clad laminate uses a thin vulcanized fibre core. It is used as a spark condenser in automobile radios. In this application the copper foil is not etched.

A relatively new use for printed circuits in the communication field is in rural carrier telephone circuits.

Air magnetic circuit breaker contains many postformed and molded paper-base phenolic laminates. The arc chute shells are fabricated of flame-resistant laminates. (Photo, I-T-E)

Other developments

Laminates impregnated with new high-temperature laminating resins have high initial strength which is retained to a remarkable degree after exposure to high temperatures. Compressor blades of jet aircraft engines are a typical application.

To provide added safety to equipment where laminates provide the electrical insulation, there have been developed a number of grades with flame retardant properties. These include various types of paper-base phenolic laminates, glass-base epoxy laminates, and glass-mat polyester laminates. In some instances, it is possible to provide this flame-retardant quality in postforming grades of laminates.

By using different variations of established laminating techniques, decorative thermoformable styrene sheets are being produced by laminating reverse-printed overlays to the surface of the sheet.

Finally, it is of interest to laminators to note that the radio-electronics-television industry

which uses numerous types of laminates experienced a growth of approximately 15% in 1956. This expansion places it in the category of one of this country's outstanding growth industries and fifth in size in dollar value of goods shipped—making it a big and important market for laminate material.

REINFORCED PLASTICS

All laminated structures molded in their final form, whether sheet, rod, tube, or contoured part, at pressures under 400 p.s.i. are called low-pressure laminates. This category can include items made at "contact" pressure or at no greater pressure than that exerted by the weight of the individual layers of the laminate. Low-pressure laminates, generally fibrous glass-reinforced polyester laminates, are usually included under the over-all heading of "reinforced plastics." The term also includes those laminates made by matched metal molding processes in which pressure higher than 400 p.s.i. is used, and more recently, the description "reinforced plastics" has been extended to further include premix molding compounds that can be molded by conventional compression molding techniques.

Actually, any combination of moldable plastics material and sheet or fibrous reinforcement is a "reinforced plastic," but the term is usually used to imply a "fibrous glass-reinforced plastic."

Polyesters are the most common laminating resins used in this area because of their relatively low cost, ease of handling, and generally satisfactory performance. Epoxy resins produce stronger laminates, but are more expensive. However, they have been growing in popularity, particularly in the manufacture of parts for transportation applications where strength and light weight are important. Phenolic, silicone, special polyester formulations, and special formulations of phenolic and epoxy resins impart improved high-temperature properties, but are more difficult to process. And in each of these groups, literally hundreds of variations are available, tailored to meet the special needs of the fabricator.

According to the Society of the Plastics Industry, close to 140 million lb. of reinforced plastics were consumed in 1956, a 30% gain in sales over 1955. Of this amount, resins accounted for about ½ of the total. Polyester resins led the parade with total sales of about 65 million lb.; the remaining 5 million lb. was divided between the fast-rising epoxy resins (with estimated sales of about 4 million lb.), low-pressure phenolic, polystyrene, silicones, melamine, and vinyl.

The markets into which reinforced plastics are going are many and varied. One of the fastest growing seems to be the field of transportation. It is estimated that aircraft uses about 20% of the total poundage of reinforced plastics, with the boat industry accounting for about 16 percent. A considerable amount also goes into the automotive and truck industry in the form of structural and body parts, as well as accessories, e.g., heater and air conditioner housings molded of premix materials. Reinforced plastics have also found important outlets in the construction field, for tooling, for pipes, and for such consumer products as sleds, fishing rods, luggage, automobile bodies and component parts, etc.

Machining Laminates

BY GEORGE A. EBELHARE*

Laminated plastics—whether in the form of sheets, rods, or tubes —are readily and easily machined on standard metal and woodworking machinery. Because these materials have many fundamental properties not common to metals, they are often considerably easier to machine than metals—with the exception of glass-base laminates, which require special techniques. With this one exception, laminated plastics have lower shearing strength, permitting the use of high cutting speeds and feeds even on machines of light construction. These same properties, however, necessitate certain modifications of metal fabricating practices before they can be adopted to the machining of laminates. The properties which affect machinery techniques are as follows:

1) Laminated plastics are poor conductors of heat. This makes it necessary to cut down the amount of heat generated. Care must be taken to see that tools are properly ground and chips are removed from cutting points.

2) Being more resilient than metals, laminates require greater clearance and less rake on cutting tools.

3) Being softer than steel, laminates require tools that can remove chips faster than the tools used in machining metal.

4) Because of the laminated structure, certain machining operations such as drilling parallel with the laminations, or milling at right angles to them, will require additional care.

5) The laminated structure is less homogeneous than metal, making it necessary to provide backing-up plates in many operations.

6) In all machining operations on laminates, it is extremely important to keep tools sharp. For glass-base laminates, diamond- or tungsten-carbide-tipped tools are necessary. Because of the heat generated in these cases, both tool and work must be flooded in a stream of coolant, or a special corrosion-inhibiting mist lubricant can be applied to the work with compressed air.

Shearing

Most laminates may be cut by shearing with metal shears of the rotary or guillotine type (see Fig. 1, right). Up to 1/16-in. thickness in some paper-base materials and up to 1/8-in. thickness in most fabric-base grades may be sheared at room temperature (minimum of 50° F.). Harder grades, including asbestos, graphite, and glass, can be sheared after heating from 200 to 250° F. (depending upon grade and thickness). With hand feeding, speed of cutting may be up to 50 strokes/min. for guillotine shearing or 600 ft./min. for rotary shearing.

Guillotine shears can also be used for angular cutting in addition to straight stripping.

When shearing grades and thicknesses that require heating, it is necessary to heat the material uniformly and to remove it from the heating medium as soon as it reaches the required temperature.

Sawing

Band-sawing: The standard woodworking band-saw may be used on laminated plastics. For most grades, the saw blades should be file-hard carbon steel; for glass, asbestos, and all other hard grades, blades should be hardened steel with soft hacks. Teeth range from 5 to 8 points/in.; and cutting speeds up to 9000 surface ft./minute.

Band-sawing is not recommended for straight cuts on material which is thin enough to be cut with a circular saw. It is recommended for curved or straight cuts on material up to 10 in. thick where smooth edges and close tolerances are not required. Blades must be kept sharp at all times.

Circular sawing: For dry sawing, the floor or bench circular sawing machines that are standard in the woodworking industry can be used. For wet sawing, machines equipped for water operation are required. For most grades, hollow-ground saws of carbon steel are recommended. The teeth should have no set and blades should be 1/16 to 1/8 in. thick with 4 to 8 teeth/in., depending on thickness and form of material. For hard grades, carbide, diamond, or abrasive saws should be used.

Laminates up to 1 in. in thickness can be sawed dry where smooth edge and close tolerance are required. Thicknesses up to 4 in. can be sawed wet, provided special equipment and care are used. Cutting speeds range up to 13,000 surface ft./min., either hand- or power-fed.

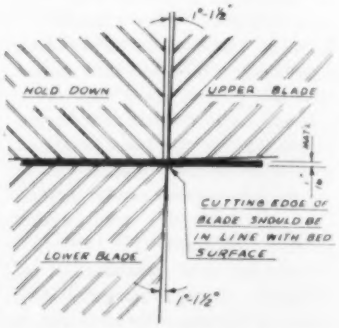

Fig. 1: Cross-section of metal squaring guillotine shears used for cutting laminates. Relative position of blades and hold-down are shown

Small tubing may be cut by feeding the material straight through the saw. Heavy-walled tubing over ¾ in. in diameter should be "rolled" through the saw to prevent excessive breakout.

A special long-length circular saw to cut sheets up to 38 in. wide and 25 ft. long has been developed by one company. Equipped with diamond or abrasive cut-off wheels, tungsten-carbide-tipped

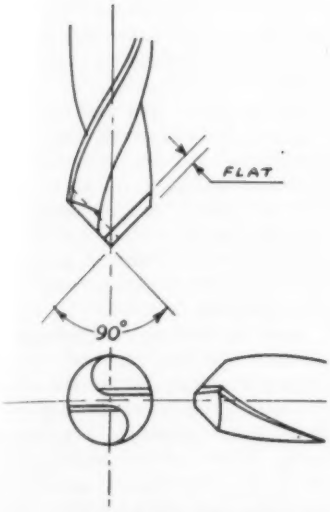

Fig. 2: Drills should be especially designed for work on plastics laminates. They should have high helix angles and wide flutes

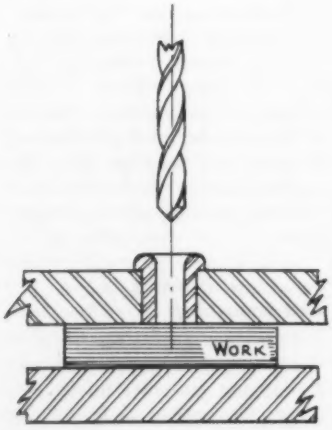

Fig. 3: Drill jig must be accurately located so drill does not strike bushing

wheels, or high-carbon steel saws, depending on the material to be cut, the new saw permits the production of planer-smooth cuts on materials up to 4 in. thick.

Drilling

Drills especially designed for use on laminated plastics are now available (see Fig. 2, above). These drills are made of high-speed steel and have wide, highly polished flutes with a high helix angle. Carbide-tipped drills should be used for hard grades.

Since the material shrinks somewhat after the drill is removed, it is necessary to drill holes 0.002 to 0.004 in. oversize or to ream the hole to the size required. The use of well-designed drill jigs in which the work is clamped between top and bottom plates (see Fig. 3, left) will insure an accurate and clean job. When top and bottom plates are not used, all holes should be backed with a piece of wood or plastic to prevent break-out and to insure a clean, sharp hole.

Drilling parallel with the laminations should be avoided whereever possible. If drilling must be done in this manner, the work should be held in clamps or a drill jig.

Drills should be kept perfectly sharp. Frequent backing of the drill from the hole will aid in removing the chips and decrease the heat produced.

Most laminates are drilled best without lubricant. In drilling glass-base grades, however, the work should be flooded with water coolant or with special corrosion-inhibiting mist sprays to decrease both dust and heat. Recommended drilling speed is 400 surface ft./minute.

The tolerances on drilled holes will vary with the diameter of the hole and grade of material. With proper care, tolerances as close as ±0.001 in. are obtainable.

Tapping

Tapping procedure has been standardized for all types of materials. A ground, high-speed steel tap is recommended. This tap has 3 flutes and for use with all laminates should be 0.003 to 0.005 in. oversize (see Fig. 4, right). Drill sizes should be selected so as to leave approximately 75% of full threads. Class 2 fits are practical in laminated plastics. No lubricant is needed under normal conditions.

Flycutting

Flycutting is generally employed to cut disks or large holes not practical for drilling. Tools are designed so that the center post holding the cutter bar can be used as a pilot in a previously drilled hole to steady the bar during the cutting operation. Cutting tools must have clearance both in front and inside of the cutting edge. Recommended cutting speeds are from 300 to 400 ft./minute.

All laminates can be countersunk or counterbored. The cutter should carry a negative rake of from 0 to 10°, and cutting speeds should be approximately half those used in drilling. Initial contact with work should be light in order to cut the highly polished surface without cracking it. If chattering occurs, a slower speed may correct this condition.

Milling

All laminated phenolic materials can be milled, using standard milling cutters. (See Fig. 5, below). For longer life between sharpenings, however, carbide-tipped cutters are recommended. Cutting speeds given below are based on carbide-tipped cutters and should be reduced approximately 25% for high-speed steel cutters.

For most grades, cutting speeds of 800 to 1000 surface ft./min. are satisfactory. For glass and asbestos, speeds should be reduced by about half. Feeds may

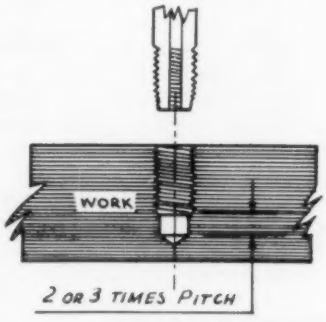

Fig. 4: High-speed steel taps with three flutes are recommended for laminates. Note depth of drilled hole

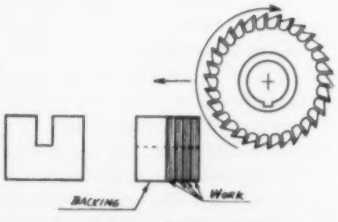

Fig. 5: Backing support during milling prevents delamination problems in the laminate

be up to 20 in./min. depending on the finish required. For fabric cotton-base materials, best results are obtained by operating at the highest spindle speed the cutter will stand, with the maximum possible feed, to give desired finish. Almost all types of milling should be done by the "climb method" (see Fig. 6, right) to prevent the edges of the material from being raised, to hold the work tightly in the fixture, and to clean the chips from in front of the cut. When cutting across the laminations, backing plates of hard wood or other suitable materials are recommended. Coolant should be used when cutting the hard materials.

Because of their generally greater ease of machining, as compared with metals, laminates are ideally suited to be worked on by air-actuated fixtures and holding devices.

Gear cutting

Gears with any of the standard types of teeth may be cut from plastics laminates. Tubing or rods are never used. Teeth may be formed in blanks by hobbing, shaping, or milling, using standard metal gear-cutting machines. The highest speed and feed of the machine should be used. Special gearing may be installed to increase surface speed and feed mechanism to rates greater than those commonly employed for cutting metal.

In cutting teeth in laminated gear stock, the last blank must be backed up to prevent fraying and break-through.

Screw machines and turret lathes

Hand-operated and automatic screw machines are highly productive in machining laminated plastics, and operate the same as for brass, except at much higher speeds and feeds. Production from these machines ranges from 1000/hr. down, depending on the job requirements.

Laminated phenolic cams are economically used on automatic screw machines where tool pressures are not too great. Speeds range up to 3000 r.p.m. for hand-operated screw machines and up to 7000 r.p.m. for automatic machines. Any desired feed can be used, depending on the finish required.

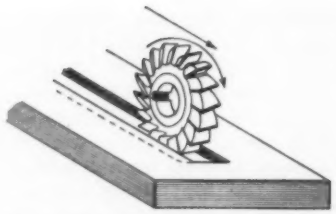

Fig. 6: Climb milling also prevents delamination. Standard cutters may be used

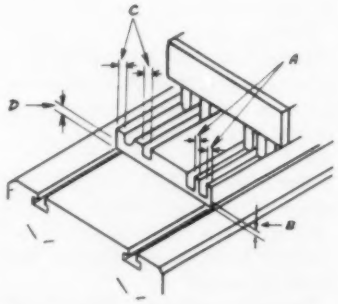

Fig. 7: Examples A and B show poor design, not enough material remains; at C and D ample material remains

Turret lathes are operated at their top speeds for most jobs within their capacity. The operations are approximately the same as those used for working with brass, except that much higher speeds and feeds are involved. High-speed steel and carbide-tipped tools are used, ground approximately the same as for brass, with spindle speeds up to 1500 r.p.m. and peripheral speeds up to 3000 surface ft./minute.

Most screw-machine and turret-lathe work is performed dry, but for deep-hole drilling, threading, etc., a coolant should be used. Forming and undercutting can be performed successfully, but care must be taken to use an extremely fine feed, preferably not over 0.0005 in. to 0.001 in./revolution. Many attachments, fixtures, and magazine feeds can be employed.

Lathe operations

Engine lathes or production lathes are generally used. Turning, boring, recessing, and any other lathe operations can be done successfully. For internal threading, and when cutting the hard materials, it is advisable to use lubricant or coolant.

Speeds up to 3000 surface ft./min. can be used, with any desired feed, depending on finish required. High-speed, carbide- or diamond-tipped tools are used for turning, boring, facing, and cutting-off. Tools should be ground from 0 to 10° negative rake for threading and forming.

Lathe operations on laminated plastics are approximately the same as for brass, except that the surface speed can be higher. Fabric-base materials can generally be worked with high-speed steel, but for paper, graphite, asbestos, and glass, carbide- or diamond-tipped tools should be employed whenever possible.

Planing and shaping

All grades of laminated plastics can be shaped and planed, using standard metal-working planers and shapers, but care must be taken to prevent weakening (see Fig. 7, left). When cutting across the laminations, the end of the cut should be backed up to secure a clean edge. This precaution is not necessary when planing parallel to the laminations.

Punching, shaving, and broaching

Punching: Sheets up to 1/16 in. thick in some paper-base materials and up to 1/8 in. thick in most fabric grades can be punched cold (minimum of 50° F.). Glass-base grades can be punched cold in thicknesses up to 1/8 inch. All other materials must be heated before punching, using hot plate, oven, hot oil, or infra-red lamps. The degree of heat to be used depends entirely on the thickness and grade of material. In most cases 120° F. is high enough, although occasionally temperatures as high as 250° F. are required.

Laminates cannot be punched to extremely close tolerances because of the normal contraction of the material and because of its thermal contraction when punched hot. Satisfactory holes are difficult to punch if the distance between hole or between holes and edge of material is less

than 1.5 times the thickness of the material. (For the best punching designs, see Fig. 8, below.)

Shrinkage allowances must be taken into consideration when designing tools. In punching 1/16-in.-thick laminate material, piercing punches should be 0.002 in. over drawing dimension. Sides must be smooth, straight, and free from annular grooves or tool or grinding marks. Die and stripper clearance should be 0.001 in. on a side. Close stripper clearance is necessary to prevent delamination when piercing punch is withdrawn from hole. Approximate shrink allowance should be 0.002-in./inch.

Progressive, compound, and multiple operating dies, including combination blanking and shaving dies, are used. Dies are practically the same as those for metal except that little clearance is allowed between punch and die and punch and stripper plate. Carbide dies should be used for glass if the quantity involved permits the additional expense that has to be undergone.

Manual or mechanical feed, with automatic stops and gages, can be used. When practical, rotary-table feeding mechanism with vacuum or mechanical pick-up may be employed.

Shaving: When smoother edges than can be had by punching are required, a shaving operation can generally be used. For irregularly shaped blanks too thick to punch, shaving will give the desired shape accurately and rapidly. Oversize cut blanks are employed in this operation.

Combination punching, blanking, and shaving dies can be used for laminates up to 1/8 in. in thickness. These dies are commonly known as "double decker" dies, and the blanked piece is pushed through the shaving cutter on the same stroke as the blanking operation.

Broaching: Broaches can be used to produce square, hexagonal, and other polygonal holes, irregular shapes, key-ways, etc. The laminated structure makes it necessary to use a special broaching procedure.

When the cutting is to be across laminations, material must be backed up with a mild steel or brass plate which forms a slide fit with the last cutting tooth on the broach. This helps prevent fraying and breakout. When cutting is done parallel to the laminations, a fixture applying pressure at right angles to the laminations should be used. Ample chip room between the teeth of the broach should be provided, based on the depth of cut per tooth. A cut of 0.001 to 0.005 in. per tooth can be taken with the pitch ranging from 1/4 to 3/4 in., as determined for the material and the particular type of operation.

Sanding and grinding

Laminated plastics can be sanded on a belt or disk sander. Surface sanding on drum-type machines may be used to finish work to extremely close tolerances and to insure parallelism of opposite surfaces. Double-spindle grinders can be used for grinding two opposite parallel surfaces at the same time. In such instances, the work is placed in a fixture which is pushed between the wheels.

Sanding may be either dry or wet. Dry sanding makes use of a relatively coarse paper (120 to 160 grits to the in.). If a finer finish is desired, the sanding machine must be adapted for wet operation. This means that the work must be cooled with water or other coolant. Otherwise, the heat generated would cause particles of resin to embed themselves in the abrasive cloth. With wet sanding, paper as fine as 180 or 220 grits/sq. in. may be used, providing a so-called "satin" finish.

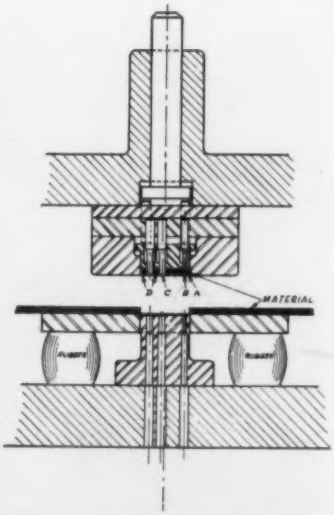

Fig. 8: *A* and *B* are poor punching designs, *C* and *D* are better (punch is larger)

Other types of finishing

Included under this heading is burring, tumbling, cleaning, and buffing, all or some of which are generally necessary to finish a fabricated part. Much of this work may be by hand, in order to remove completely objectionable burrs and fuzz.

Various polishing agents can be used in "tumbling" fabricated pieces in standard revolving barrels. Buffing with standard rag buffing wheels will give the material a smooth finish, and the use of rouge will be helpful in restoring high polish to machined surfaces.

Grinding tubes and rods

A centerless grinder, equipped with a silicon carbide wheel running at a surface speed of 9000 ft./min. is used for finishing rods and tubes. In addition, a vertical belt sander is used for finishing operations on many types of tubing. The grit size is determined by the finish desired. To obtain a buffed finish, a "slick" belt run at about 4000 to 6000 surface ft./min. is used with a suitable compound.

Molding Reinforced Plastics

BY HARRY T. DOUGLAS*

The term "reinforced plastics" basically refers to any plastics materials containing reinforcements of one kind or another. In its broad sense, it even covers such products as high-pressure decorative or industrial laminates. Trade usage, however, has relegated the description "reinforced plastics" to those reinforced plastics materials that can be molded into *complex* shapes and sizes with pressures ranging from simple contact to the higher forces generally involved in matched die molding. Since the major volume of reinforced plastics produced are manufactured with thermosetting polyester resins reinforced with fibrous glass, it is this combination that is generally implied when one speaks of reinforced plastics.

Resins and reinforcements

Polyester resins, the most widely used resins in the field of reinforced plastics, harden by chemical change and are not subject to resoftening or reforming. As the resin is received, it is somewhat viscous. However, the degree of fluidity can be controlled and adjusted by the addition of styrene which joins in the reaction and does not volatilize. Various catalysts are used to bring about the desired reaction and the subsequent hardening of the resin, either with or without pressure and externally-applied heat.

The popularity of the polyesters is based on their unique properties. They are easy to handle, can be applied by a doctor blade, or even poured or painted on the fibers. The cure is a complete reaction as nothing is given off in the way of volatiles or condensates or taken on during the curing cycle The resin can be used with or without pressure and with or without heat—making it possible to manufacture almost any size product in lightweight, low-cost molds.

To develop the great strength of the reinforced plastics product, however, glass or other fibers must be used for reinforcements, much as steel rods are used in concrete. The polyester resin acts as a binder to transfer loads through the cured and hardened resin to the stronger reinforcing material. There are several kinds of glass fibers used in the laminating process: 1) roving, a spool-like package of continuous glass strands which is most suitable to applications where unidirectional strength is required; 2) yarns, which can be twisted together and woven into a great variety of fabrics; and 3) fibrous glass mat, a random accumulation of cut strands rolled into sheets.

The impregnation of woven glass cloth or fibrous glass mat or rovings with polyester resin, plus the application of a catalyst results in a strong, dimensionally stable, lightweight material ¼ the weight of steel and about ⅓ the weight of aluminum. The physical properties are about the range of other plastics and compare favorably with metals. Strength/weight ratio in tension and compression is better than steel and about the same as magnesium. It possesses outstanding impact resistance, durability, corrosion- and rust-proof characteristics, and has superior arc resistance, low dielectric constant, and good power factors.

In recent months, considerable work has been done with the use of resins other than polyesters (e.g., epoxies, etc.) and with the use of fibers other than glass (e.g., synthetic fibers, asbestos, etc.) either by themselves or in conjunction with glass.

Apart from glass fibers, probably the highest volume of fibers now being used are sisal and asbestos, primarily in the field of premixes and prepregs. Although some strength is lost, sisal offers low-cost, medium-impact properties and high bulk. For a variety of applications, such as furniture frames for upholstered pieces where cost might be a prime consideration, sisal can be

Matched metal molds are used primarily for quantity production runs where faster production rates can offset initial high cost of the molds. (Photo, Lunn)

Recent Developments and References were prepared by the editors.

substituted completely or as a part of other materials in the reinforcement.

Bag molding

Reinforced plastics products really came of age with the development of "bag molding." In this process, a flexible bag or blanket, such as a polyvinyl alcohol or rubber blanket, is placed over the plied layup and either pressure is applied against the layup or a vacuum is drawn between the bag and the mold during its curing cycle to remove excess resin and air.

The layup consists of impregnated layers of fibrous glass fabric placed in a mold. Unskilled labor can easily be trained to do the work.

In order for the fibrous glass mat to become a part of the laminated product, resin is applied by rollers or poured from a container onto the layup and distributed carefully. The parts are then cured by heat or through the stimulation of a suitable catalyst.

Autoclave: By the autoclave molding method, steam or air may be used as a source of pressure on the layup material after vacuum has been drawn. The mold and layup are placed in the autoclave and pressure applied in the closed chamber. It is essential that no leaks exist in the bag or between the bag and the mold because the steam or air will be forced into the laminate causing spoilage.

Pressure bag molding: This process, a variation of the autoclave method, consists of a tight-fitting cover over the bagged layup which allows the introduction of increasing pressures on the laminate.

Contact molding: In those applications in which relatively low-volume runs are called for, max-

RECENT DEVELOPMENTS

A new type of press and mold (Sterling Precision Corp., Fibre Glass Plastics Div.) is capable of mass production of large reinforced plastic shapes by a process which makes void-free moldings. The new technique is equivalent to metal-die molding but is free of the physical limitations in tool cost and production methods inherent in the process. Parts of practically unlimited size and depth of draw are possible, and close dimensional tolerances and uniform physical integrity can be maintained. Automobile tops and trailer bathtubs are already being molded by the new method.

A reinforced plastics swimming pool (Delorich Enterprises, Inc.), 84 ft. long, 36 ft. wide, and from 3 to 11 ft. deep, built for the Red Lion Country Club in York, Pa., is probably the largest reinforced plastics item ever fabricated.

A new flexible glass fabric-reinforced polyester (*Conoglas,* Continental Can Co.) has been developed for lining bins, tanks, freezers, freight cars, trucks, and similar food storage and shipping containers. The material imparts a durable, wear-resistant, stain-resistant, and waterproof surface to containers, will not support the growth of mold or fungus, and is unaffected by alcohol, mineral acids, vegetable oils, salt water, weak alkalies, toluol, heptane, carbon tetrachloride, and other chemicals. It is available in rolls up to 150 ft. in length or in cut-to-size sheets.

Production of 1600 air conditioning ducts was accomplished in 17 days in a reinforced plastics mold, 53 in. long, 22 in. wide, 10 in. high, and weighing 1000 pounds (Apex Plastic Co.). This method of plastics tooling for molding is capable of producing as many as 10,000 to 12,000 pieces in matched plastics molds for short-run jobs or whenever it is essential to have finished pieces before the metal molds can be built.

A pre-impregnated fibrous glass-reinforced phenolic laminating material (*Conolon 506,* Narmco Resins & Coatings Co.) was developed specifically for ease of handling, curing, and fabrication in the production of aircraft components which must perform at elevated temperatures over extended periods. In fabricating structural components with this material it is necessary only to cut the desired pattern from pre-impregnated "B" stage laminating material, lay up the material, and cure the final part. It cures at pressures as low as 15 p.s.i., and can be fabricated on inexpensive disposable molds.

An amber-colored, fluid epoxy laminating resin (*Epocast 17,* Furane Plastics, Inc.) used in conjunction with a hardener is suitable for low-pressure laminating of fibrous glass into structures capable of withstanding high-temperature operation No solvents or volatiles are present, and the activated resin may be immediately applied to glass cloth. The high-temperature properties of laminates using this resin are obtained by postcuring at temperatures of 400 to 500°F.

A laminating resin (*Eccomold L 65,* Emerson & Cuming, Inc.) with low loss and low dielectric constant is designed for applications such as radomes and printed circuit boards. It is a thermosetting material. Parts made from it will withstand 300° F. continuously. Another laminating material (*Eccomold L 28*) of this manufacturer is a general-purpose epoxide which has been selected for radome and laminated sheet stock applications. An epoxide material (*Eccomold L 266*) which can be used continuously at 500° F. and for short periods as high as 600° F., and a low-loss, nonflammable polyester (*Eccomold L 44*) are also available.

A thixotropic laminating gel coat (*Resin 604A,* Marblette Corp.) with fast cure and a laminating resin (*Resin 607*) are now available in premeasured quantities. They are offered in cases holding six 1-pt. cans, along with the requisite quantity of hardeners to be used.

imum strength is not a factor, and only one side of the reinforced plastics part needs a smooth surface, contact molding is recommended. No pressure is involved. The resin is applied by brush or roller, thus excluding air bubbles.

In many instances, up to 4000 parts can be economically produced by these manual methods. Above this quantity, because of the labor involved, matched die molding should be considered.

Matched die molding

To produce large quantities, matched dies, which last longer, produce more parts with both surfaces relatively smooth, turn out pieces faster, and minimize trimming and finishing steps, are used. In this technique, the reinforcing material and resin are placed in the heated molds, and the molds are brought together by pressure. Pressures used are from 100 to 400 p.s.i. The molds invariably close against stops which determine part thickness.

Although this is by far a faster method of producing reinforced plastics parts, the initial outlay for matched dies is much greater than for single male or female dies. A guarantee of a large order or repeat orders is necessary (probably in lots of 4000 or more) to make this an economical investment for the molder. In matched die molding, metal dies, although most expensive, are used because of their accuracy, long life, and the fact that they can be readily heated. Some work has been done with matched plastics dies, and a combination of metal and plastics dies, but it is difficult to predict the life of these molds. They do not transmit heat quickly, although they are cheaper to manufacture.

The longer life of matched dies and the faster production rates often make the higher initial investment rewarding. Shorter molding cycles result in lowered labor cost, and product thickness is more easily controlled.

The smooth surface is due in part to die finish but mostly it is the result of overlays. With new research and development nudging production progress, larger pieces are possible now which were unknown even a year ago: larger boat hulls; one-piece lavatory units consisting of toilet, sink and wall section; double-shell seats; more decorative translucent lighting panels; and sectional room dividers.

Vacuum injection molding

There are several methods employed in matched molding. One of the early milestones in the field of reinforced plastics is vacuum injection molding. This is still used by industries where speed in production is not essential, e.g., in making limited quantities of sample parts.

Primarily the process was developed as a solution to making large parts on inexpensive molds and producing good inner and outer surfaces. These molds were usually of plaster, reinforced plastics, or metal with smooth inside surfaces. The best feature of this method is that the male and female mold surfaces produce a finished part with a smooth finish, eliminating bag wrinkles, and lending itself to limited production. If a larger quantity order later develops, matched metal dies are the next logical step.

In vacuum injection molding the male mold is constructed incorporating a recess or lip into which the base of the female mold sets. The female mold has one or several vacuum outlets on top permitting air evacuation.

Care should be taken that, when the female mold is lowered, there is no mismatching. To offset any misalignment in the mating of the molds, guide pins should be used.

The vacuum action commences after a room temperature resin is introduced into the recess or lip. The resin is drawn up from the recess and impregnates the reinforcing material. Not more than one foot of mercury is necessary; otherwise, bubbles might develop from the boiling of the styrene.

The resin impregnates the laminate evenly if the material is distributed uniformly. Properly done, it becomes practically a void-free laminate. When the resin appears through the sight gage the vacuum should be discontinued to permit the resin to harden. For easy removal of parts, back-off bolts are screwed against the product to permit lifting the female mold, and compressed air injected through the outlets beneath the male mold, freeing the finished part.

The first structure of its kind to be molded of reinforced plastics, this submarine fairweather withstands corrosion by salt water. (Photo, Lunn)

An interesting advantage of this technique is that it is possible to make an almost transparent mold which gives a visual picture of the resin being drawn through the laminate and up to the top of the mold. This helps in determining when to turn the vacuum off at the proper sequence. It is very often advantageous to clamp off the vacuum several times during the operations to let the resin level out by gravity and prevent channeling. This offsets the tendency of the resin to go directly to the vacuum port and leave large voids. When building the required number of plies and before molds are clamped, it is also an advantage to include in the lay-up a stiff and springy ply of mat which accommodates the passage of resin.

Additional considerations in favor of vacuum injection molding are: producing large, intricately shaped parts on inexpensive molds; molding parts with varied wall thicknesses; making reinforcements, ribs, and other interior structures as part of one unit; eliminating as large an amount of finishing as may be necessary in bag molding opera-

tions; using inexpensive equipment; and saving on materials by permitting a closer control of the resin and glass supply.

Some of the disadvantages to note are: the time element involved in the initial lay-up and molding the part; the low resin-to-glass ratio; the inconsistent rising of the resin to the top of the mold; the additional cost of a male or female mold; and the chances of a leak occurring during the molding cycle which would be difficult to locate during cure and which would subsequently produce a damaged piece.

Injection molding

Another method of matched die molding extensively used is injection molding of reinforced thermoplastic molding compounds, where volume production is called for. By arranging cavities in series, it is possible to produce simultaneously the various component parts in an assembly. The disadvantages of the technique are the considerable capital outlay and the high die cost and setup time.

From the elaborate preparations necessary in this type of production, it is easy to see that production should continue without interruption for an extended time. In some cases, an entire week is involved in the run of just one set of parts. The order must be a sizable one to offer a sufficient return on this costly investment.

Although other thermoplastics are used, the most suitable reinforced plastics material for this specialized type of molding is polystyrene containing fibrous glass strands with the reinforcing compound in pellet form. This method produces rigid parts resistant to changes of temperature and possessing excellent tensile and flexural strengths. Increasing uses in the military field for numerous parts made by pressure injection molding have expanded the market for many applications of this technique.

Depending on the product design and weight, the average operating temperature might be from 450 to 600° F., with corresponding cycles of 120 to 30 seconds. Higher temperatures often cause discoloration. On the other hand, cold molds for short cycles produce inferior parts with surface imperfections, and it is advisable to heat the mold surfaces to approximately 180° F. by hot water or oil circulating through the mold surface. Adequate pressures are imperative on the reinforced plastics materials in the molds as a slight miscalculation can ruin a large number of parts set up in the various cavities.

Premixes and prepregs

Leading the way into expanded new uses for reinforced plastics is the group of premix compounds. These plastics compounds possess different characteristics than the laminate materials.

Laminated products, on the one hand, are formed by pouring or rolling the resin on the fibrous glass mat, whereas with premix plastics compounds, these materials are mixed together before the molding process. Complex and unusual shapes with varying cross-sections, which would be difficult to attempt with a laminating method, can be molded with premix materials. The physical strength is substantially lower for premix compounds, but where this is not an important consideration in the finished part, or where thickness can be substituted for high unit strength, premixes can be used to obtain such advantages as: good contours at low molding pressures; dimensional stability; weather resistance; stable dielectric properties; and high impact strength.

Another time- and labor-saving development which is substantially gaining ground in the reinforced plastics field is prepreg molding. This utilizes fiber or other reinforcing materials which have been pre-impregnated with a catalyst resin and can be cut into patterns very readily. Prepregs have been widely used in other molding operations and their easy workability in the reinforced plastics industry have given these materials an added impetus as labor-saving devices. All resin calculations, mixing, and applying are eliminated. The improved resin usually selected is a diallyl phthalate type which has the added advantage of not only being tack-free, thus making it cleaner to work with, but also has the facility of readily adhering to itself and allowing easy build-up of ply.

Pre-impregnated materials can be made up of fibrous glass mats, paper, cotton, linen, or synthetic woven fabrics, with the selection of a specific resin depending on

Low-pressure contact molding techniques are used to turn out this reinforced plastics section for a Geodesic dome. After molding, parts need only be trimmed to be readied for installation. (Photo, Lunn Laminates)

the final usage. Storage life of the prepreg materials has extended to six months and longer in some instances.

The even distribution of the resin helps turn out better-made parts. Less waste also occurs with this material because it is easier to handle than untreated glass cloth. Although prepregs are more expensive than standard materials, the considerations in favor of estimated time saved should be investigated by the molder to ascertain whether this is applicable to his individual needs.

Dies

The selection of dies for molds is dictated by the kind of manufacturing the reinforced plastics molder intends to follow. Should he start with bag molding, dies constructed of plaster, plastic, or metal could be utilized depending on quantity, quality of parts, and the economics of the part run.

Plaster dies have an extra short life and are used primarily in making prototype parts. Dies of reinforced plastics utilizing polyester or epoxy resins, often filled with metallic fillers, have been used successfully in pilot productions.

High-volume manufacturing demands the use of aluminum or steel dies which produce parts with close tolerances and turn out products quicker and with a comparatively smooth finish. Machined and polished aluminum dies have yielded up to 10,000 pieces.

Aluminum dies are used to mold small radomes for housing military products and shell structures. (Photo, Lunn)

Some of the present objects made with aluminum dies are: safety helmets, military chest protectors, office fixtures, aircraft and marine parts, and trays.

Steel dies, though more expensive than aluminum, have excellent strength properties and lon life. The surfaces are painstak ingly machined to eliminate eve the minute imperfections. Th use of steel dies has pushed th reinforced plastics industry so fa ahead that products manufac tured through this process hav replaced completely other stand ard materials.

Among the numerous articles produced through this technique are: guided missile parts, pleasure craft, automobile and truck body parts, fruit and vegetable crates, tote boxes, trays and furniture.

Hood for outboard motor is matched metal molded in a 150-ton press. After molding, hood is sprayed with a special melamine-base enamel paint that requires subsequent oven cure for final hardening. (Photo, General Tire & Rubber)

Preforming Fibrous Glass

BY W. W. THOMPSON* and R. G. ADAMS*

There are three basic methods which have been developed for the preforming of fibrous glass. They are: 1) plenum chamber; 2) directed fiber; and 3) water slurry.

Plenum chamber

The plenum chamber method is perhaps the most widely used process. Fibrous glass rovings are fed into a cutter where they are cut to lengths between ½ and 2 inches. The 2-in. cut is most often used, although shorter cuts, or a combination of cut lengths, are also in common usage. From the cutter the fibers fall into the plenum chamber, or into a chute that carries them into the plenum chamber. They are deposited on a perforated screen as the air is exhausted from beneath the screen. (See illustration, below.)

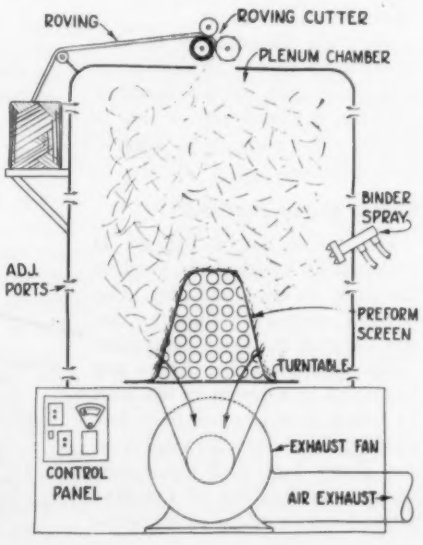
To help insure a uniform deposition of strands, the preform screen rotates. In addition, internal baffles on the screen are frequently used to aid in the proper deposition of fibers. A resinous binder, which may be either a powder, or a liquid, is applied at the same time the glass is being deposited. Liquid binders, usually polyester and water emulsions, have been found to be the most satisfactory for the majority of applications.

The cutter acts as a feed mechanism for the glass; thus glass input can be controlled by a timer. The input of the resinous binder can also be controlled by a timer, although manual spraying is occasionally used.

The plenum chamber machines are the most nearly automatic of the air-type preformers and thus produce the highest rates of production. Their operation is somewhat cleaner since they are enclosed. A big advantage of the plenum chamber method is that once it has been set up to do a particular job, very little operator skill is required to get reproducible results throughout a production run.

The disadvantages center around the long setup or tryout time which may be required whenever a new part is started in production. This is due to the fact that the fiber deposition depends entirely upon the correct flow of air through each part of the screen. To achieve this, intricate baffle systems within the screen often have to be developed. This setup period can take several days.

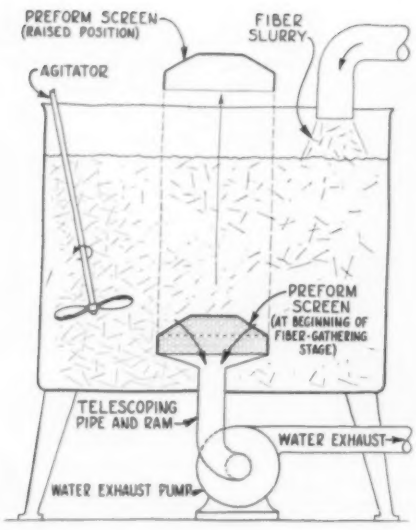
The plenum chamber machine is therefore most adaptable for applications for which it can be set up to run off a part continuously for a long period of time.



Directed fiber method

In the directed fiber method there is no plenum chamber over the screen. The preform screen is located on a nearly vertical turntable behind which is located an exhaust fan. The cut fibers are directed at the preform screen from the flexible hose of a separate cutter unit. The cutter unit consists of a roving cutter, a blower provided with a venturi where the cut fibers are introduced, and a flexible hose.

The rovings are cut in the roving cutter, dropped through a short duct, and are introduced into the venturi air stream, which blows them out of the flexible hose. The operator directs the stream of fibers at the slowly rotating preform screen on the turntable. The binder is simultaneously sprayed onto the piece by the operator.



While the glass input is controlled by a timer, considerable operator skill is required to produce uniform preforms. He controls the distribution of both fibrous glass and the binder on the screen, and therefore the quality of the part. Where relatively lightweight preforms are being made, the operator can be aided by a strong light behind the preform screen.

One of the chief assets of the directed fiber method is that, given a skilled operator, a part can usually be put into production within a few hours after the preform screen is delivered. Baffling is seldom necessary in screens since a good operator can direct the fiber stream to any part of the screen. In the same manner, the operator can allow for varying part thicknesses where the changes are not too abrupt. It is also quite easy for the operator to add inserts, mat build-

Most nearly automatic of the air-type preformers, plenum chamber machines yield highest production rates and, once a job has been set up, require very little operator skill to get reproducible results throughout a production run

* Owens-Corning Fiberglas Corp., 598 Madison Ave., New York 22, N.Y.

Although a higher capital investment is required for the water slurry preforming method, the technique has many advantages: it is more automatic, faster production cycles can be achieved, and intricate shapes, abrupt changes in wall thickness, and very heavy walls are all possible

ups, or wire beads to the preform. Even in instances when a wide variety of different parts is to be made and change-overs are frequent, the directed fiber method is still adaptable. Several different sizes and shapes of parts can be run one after another on the same machine. The only adjustment the operator has to make is to set the proper cutter time for the part. (See illustration, below.)

This method has been shown to be adaptable to making very large parts, up to 120 sq. ft. in area, and over. The directed fiber method is also useful in preforming odd-shaped parts, such as a very long and narrow piece or large pieces with considerable open area in the center.

Although theoretically capable of the same rate of production as a single-station plenum chamber machine, a slightly lower rate is usually experienced with directed fiber machines.

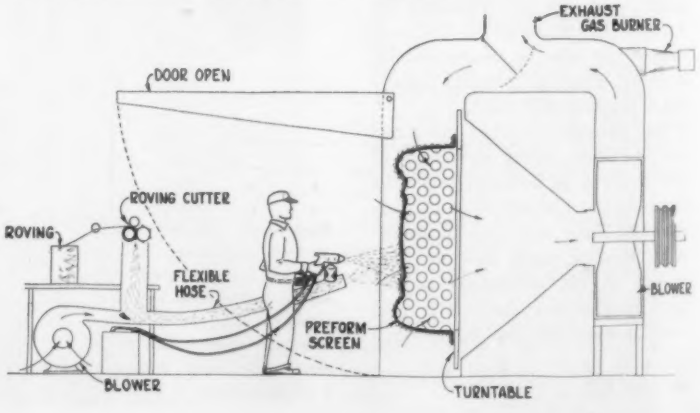
Water slurry method

The water slurry method is very similar to methods used in the pulp molding industry. The chopped strands of fibrous glass are slurried in water containing cellulosic fibers. The fibers are deposited on a screen in the bath as water is exhausted from beneath it. The screen is raised from the slurry bath and the excess water is sucked out of the preform. Various ratios of glass-to-cellulosic fibers can be used although 80% fibrous glass and 20% cellulose seem to produce good results. (See illustration, above.)

Although it has many advantages over the airborne type of preform machines, the water slurry method is not widely used in the United States.

This method is the only one in which there is little or no scrap loss. It is more automatic and fast production cycles are possible. The preforms are tough and self-supporting without the addition of resinous binders. Intricate shapes, abrupt changes in wall thickness, and very heavy wall thickness are all possible. The initial capital investment for equipment is higher than for the air systems because more equipment is involved.

Although water slurry preforms handle easier than air-felted preforms, they usually have a higher bulk factor which sometimes leads to wrinkling. It is practical to use only a low percentage of filler in the molding resin because of the filtering nature of the cellulosic fibers; however, the resin can be pigmented and the preforms can be dyed for decorative effects.



Production cycles

Production cycles depend upon the following factors: 1) the weight of the preform; 2) the number of roving cutters; and 3) the amount of hand work required. Where difficult shapes are encountered, or where high quality is required, the production cycles may be 20 to 30% longer than average.

For quality work, the majority of molders cut roving at about 1 lb./min. per cutter. While the cutter can cut fibrous glass at several times this rate, the uniformity of preforms falls off considerably at the higher cutting rates. Where lower quality preforms can be tolerated, many molders cut at the rate of 2 to 3 lb./minute. These cutting rates apply to both the plenum chamber and the directed fiber methods.

In actual practice, the full capacity of the preform machines is seldom used, because so much depends on the ability of the operator to keep up with the machine.

To offset a slightly lower production rate, directed fiber machines are designed so that, given a skilled operator, a part can usually be put into production within a few hours after the preform screen is delivered

Sandwich Constructions

RECENT DEVELOPMENTS

A unique foamed styrene-and-paper sandwich material (*Fomecore Board*, Monsanto Chemical Co.) consists of a core of stiff foamed styrene with a sheet of specification kraft paper on either side. It retains high compression strength under conditions of severe humidity and provides excellent insulation qualities. A container (St. Regis Paper Co.) made of this board is light in weight and strong enough to withstand long distance shipping under the high humidity conditions of refrigerator cars and trucks.

Structural panels of phenolic-impregnated kraft paper honeycomb and polyester-paper and polyester-fibrous glass (*Conolite*) faces are now being produced in effectively continuous lengths (Honeycomb Div., Continental Can Co.). Both the honeycomb and the facing are produced in continuous lengths, with size of panel controlled by the size of the bonding press. The hot press used by the company is capable of producing panels 200 in. long by 48 in. wide.

In an adaptation of the "lost wax" process, a new thermoplastic (*Hot-Melt H-883-A*, Furane Plastics, Inc.) is used for filling honeycomb cores to facilitate later machining of stainless steel honeycomb structures. After machining, it is melted from the honeycomb and the structure is cleaned with hot water.

Plywood with a weatherproof overlay (*Crezon*, Crown Zellerbach Corp.) will be used for such products as sidings, signs, boats, and handyman panels. A resin-impregnated cellulose fiber sheet is applied to the plywood panel and then permanently fused to wood under heat and pressure.

Aircraft component is fabricated of sandwich made up of aluminum skins over aluminum honeycomb core. Lightweight structure offers sizable weight savings. (Photo, Narmco Mfg.)

Sandwich constructions are multilayered structures composed of thin, strong facings integrally bonded to comparatively thick, low-strength cores. They are often flat panels that can be fabricated into an end-product, but they can also be curved shapes, e.g., curved airplane radomes made of fibrous glass-reinforced plastics sandwiches.

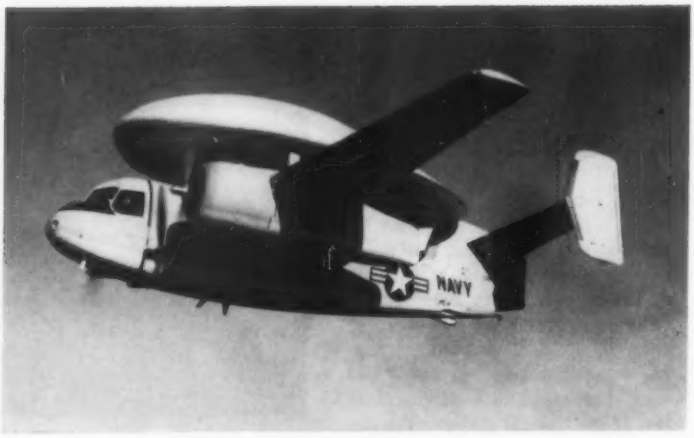
Sandwich construction materials have shown a remarkable growth within the past few years. Indeed, there are surprisingly few parts in aircraft, building construction, small boats, and many other fields which have not already had at least one prototype made out of sandwich materials. When designed as a structural sandwich, the entire assembly provides high strength and stiffness in proportion to its weight.

Introduction to this article is based on material supplied by Andrew C. Marshall, Western Regional Manager, Hexcel Products, Inc., 955 61 St., Oakland, Calif.

Recent Developments and References were prepared by the editors.

Adhesives

Much of this growth in the industry can be traced to developments in the use of synthetic resin adhesives to provide an integral, rigid, and reliable attachment between the core and the facing of the sandwich.



The bond may be effected by using the same resin as is used in the facings, e.g., polyester resin for polyester-fibrous glass facings. It may also be applied separately in the form of a tape or paste compounded of epoxy, phenolic, vinyl, rubber, acrylic, or other resins, or as is usually the case, a combination of several resins.

In designing aircraft parts where high strength and temperature stability is sought, these adhesives usually have a glass or cotton fiber skrim cloth as a carrier. The function of the cloth is not only to facilitate handling, but to improve resistance to abuse and peel failures as well. Cost of this form of adhesive can run in excess of $3/sq. ft. of sandwich.

At the other extreme are the liquid resins used for bonding architectural panels for exterior building facings that can be handled in tank trucks and spray guns. Cost in such instances is only 20¢/sq. ft. of panel. In either case, for a successful sandwich construction, the adhesive must be selected for its ability to maintain integral attachment between the core and the facing for the entire expected service life of the part.

Facings for the sandwich construction can be flat sheets of plastics, paper, wood, metal, etc.

The core materials also show wide variety. The most important job of a bonded core material in sandwich constructions is to stabilize and stiffen two thin facings having relatively high tensile strength so that the major part of a load is borne by the skins. The bonded core also converts the two skins into a single structure of great rigidity so that they deform much less under load than they would unjoined. To serve these purposes, the core must have high compressive, shear, and tensile strengths, and a fairly high modulus of rigidity in shear;

Light weight and structural efficiency, despite large size, characterize airplane radome made of reinforced plastics honeycomb core sandwich. (Photo, Hexcel)

in many cases, the core must also serve as a thermal or electrical insulator.

Honeycomb Core

BY ANDREW C. MARSHALL*

Honeycombs are among the most important types of core materials used in sandwiches today —and still growing fast. Because of its structure (based on the concept of a bee's honeycomb), it not only has great strength per pound, but also excellent thermal and insulating properties.

An estimate of 1956 core sales would break down as follows: paper honeycomb—$4 million; aluminum honeycomb—$4 million; fibrous glass honeycomb—$2 million; stainless steel honeycomb —$250 thousand. It is anticipated that the growth in 1957 will be in the inverse order of the above list, with stainless steel growing five- or tenfold and the paper honeycomb growing some 50 to 100 percent.

Some of the honeycomb uses deserve special mention. Curtain walls for the building industry, for example, are expected to show a sharp increase this year. The appearance of the optically-flat surfaces gained through the use of sandwich materials in this type of construction has already attracted attention of architects, and several office buildings and airport terminals, using as much as 75,000 to 100,000 sq. ft. of sandwich materials each, have recently been erected.

The end uses of the various types of honeycomb available are many and diverse. Most of it, however, goes into the following major markets:

Honeycomb core	*Facings*	*End uses*
Paper	Porcelainized steel	Curtain walls in buildings
	Fibrous glass	Small boats
	Wood veneer or metal	Aircraft interiors
Aluminum	Aluminum	Aircraft structures
	Porcelainized steel	Curtain walls in buildings
Fibrous glass	Fibrous glass	Radomes and antenna windows
Stainless steel	Stainless steel	Aircraft structure

Also new in the area of applications for sandwich materials are structures exposed to the intense sound damage areas in turbo-jet aircraft. Typical of these structures are the wing assemblies aft of the engine exhaust on many aircraft. Without the unique properties of the sandwich materials, it would have been virtually impossible to design a structure with reasonable weight and service life in these areas.

Another new idea in sandwich structures is the use of both foamed plastics and honeycomb materials in the same sandwich. Using this technique, local strength may be increased fourfold and a shear attachment means is provided.

Finally, the success of many types of aircraft as radar warning picket ships owes much to the fibrous glass honeycomb sandwiches of which their huge radomes are constructed. These domes are as large as a backyard swimming pool (the rotating antennas inside are approximately 18 ft. in diameter) and yet are easily carried aloft without seriously impairing either the pay-

* Western Regional Manager, Hexcel Products, Inc., 955 61 St., Oakland, Calif.

Sandwich panel used in manufacture of all-plastics refrigerator has foamed styrene core and high-impact styrene alloy sheet faces. (Photo, Westinghouse)

load or the performance of the aircraft on which they are mounted.

Among the newer developments in the offing are plastics sandwiches capable of service at temperatures of 800 to 1500° F. Adhesives are being readied that will permit applications at service temperatures of over 700° F. Fibrous glass core-aluminum skin sandwiches, already winning the competitive battle with all-aluminum structures, have also recently undergone marked improvement. Bonded primary structures based on sandwich materials and now found only in two aircraft (Convair B-58 and Temco TT-1) also show promise of becoming standard in the industry.

Balsa Wood Core

BY RICHARD MARK*

Balsa wood with its high strength/weight ratio and other advantages (see Table I, right) has been used for quite some time as a structural core for aircraft sandwich construction. More recently, the use of balsa has been extended to include many applications in reinforced plastics where thick sections are required for thermal insulation and/or rigidity. Included among these applications are: tank trailers that transport bulk milk and orange juice; ladders for use in telephone line service; pleasure craft; and others.

* Balsa Ecuador Lumber Corp., 500 Fifth Ave., New York, N.Y.

TABLE I: Characteristics of balsa wood

Forms available	*End-grain—rigid blocks*			*Flat-grain—rigid boards, panels, blocks*		
Standard sizes	Thicknesses: 3 to 29 in. Widths: 18 to 48 in. Lengths: 3 to 36 in.			Boards: Thicknesses: 1¼, 1¾, 2¼, 2¾, 3¼ in. Widths: random Lengths: 2 to 7 ft. Panels: Thicknesses: 1 to 3 in. Widths: 4 to 30 in. Lengths: 1 to 10 ft. Blocks: Thicknesses: 3 to 29 in. Widths: 3 to 36 in. Lengths: 1 to 10 ft.		
Density, lb./cu. ft.	4-9	9-14	14-18	4-9	9-14	14-18
Thermal conductivity, B.t.u./sq. ft./hr./°F./in.	0.67	0.99	1.24	0.30	0.44	0.55
Tensile strength, p.s.i.	1,745	2,630	3,500	105	150	205
Compressive strength, p.s.i.	1,020	2,090	3,080	75	125	170
Maximum service temperature, °F.	Varies with exposure time from 150 to over 500					
Coefficient of linear expansion, 10^{-6} in./in./°F.	0.199			0.776		
Moisture absorption, % by wt.	High alone; very low when part of sandwich structures					
Water-vapor transmission	Approx. 1.15 grains/da./sq. ft./mm. Hg for 1-in. thickness					
Dielectric constant	< 1.5 at $10^2 - 10^{10}$ cycles per second					
Dissipation factor	< 0.01 at $10^2 - 10^{10}$ cycles per second					

Because of its rigidity, the largest use for balsa cores has been in flat panels or straight beams. More recently, techniques have been developed for using it in curved structures.

Trimmed, curved end-grain balsa wood core sandwich is produced by laminating one skin to the core prior to bending. The balsa wood core is ½-in. thick. (Photo, Balsa Ecuador)

Foamed Plastics Cores

Foamed plastics also stand out as a lightweight, thermal insulating, and acoustical insulating core for sandwich materials—either as a foamed-in-place core or as a block or sheet of plastic foam cut to size and cemented in place between the two faces. Considerable attention has been attracted by a sandwich material made up of two sheets of high-impact styrene sheet laminated to a foamed styrene core and recommended for use in food processing plants, bakeries, etc., as a curtain wall in building, as a liner for refrigerator doors, etc.

For a complete review of the various types of foams available as core materials, see the Foamed Plastics Section, p. 334.

PRODUCTS COMPANY

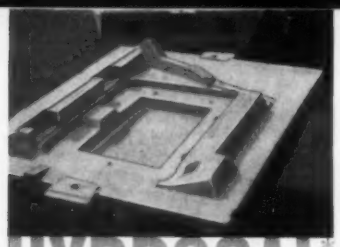
ST. CHARLES, ILLINOIS

LONDON, ENGLAND • SYDNEY, AUSTRALIA • BUENOS AIRES, SOUTH AMERICA

Now...from U.S.G.

the most complete line of materials for plastic tooling!

U.S.G. experience, technology and research set new standards for epoxy laminating and casting resins



Now, you can do the entire job—from blueprint to finished pattern or tool—with materials from a single source, United States Gypsum. The addition of new EPOXICAL Tooling Plastic to the U.S.G. family of gypsum cements and plastics completes a line of materials for laminating and casting; makes U.S.G. an important part of the plastics industry.

Now, you're assured of unit responsibility; of quality materials that have been scientifically researched, thoroughly tested. A qualified U.S.G. technician will be happy to demonstrate how these U.S.G. materials can be applied to your plastic tooling problems.

FREE! Write United States Gypsum, Dept. 122, 300 West Adams St., Chicago 6, Ill. for this free literature: HYDROCAL Models and Molds (IGL-ITT-100); Vacuum Forming with ULTRACAL (IGL-ITT-55); EPOXICAL Laminating Resin (IGL-400); EPOXICAL Casting Resin (IGL-401).

USG UNITED STATES GYPSUM

UNITED STATES GYPSUM

HYDROCAL*

HYDROCAL gypsum cements are used for molds and original models to laminate or cast plastic patterns, dies, jigs, fixtures or foundry match plates and core boxes.

ULTRACAL*

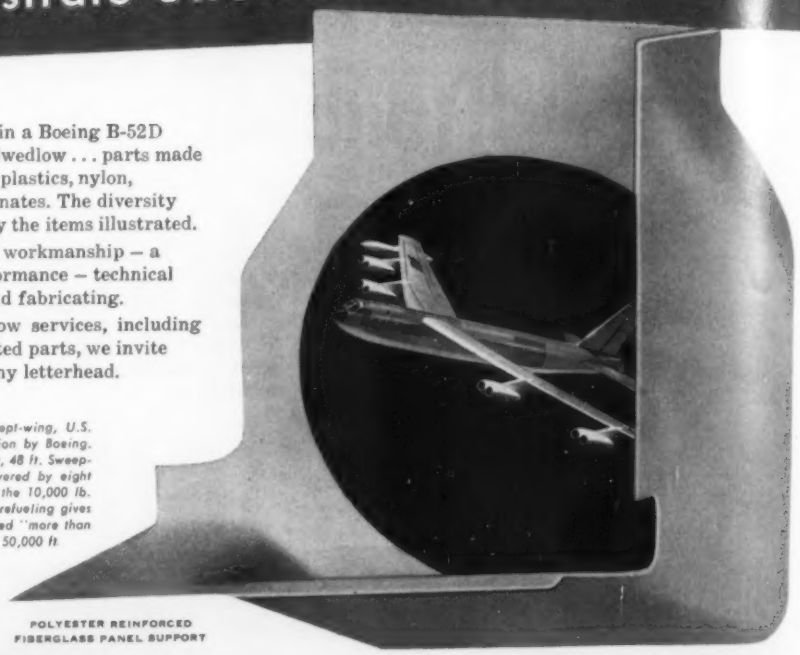
ULTRACAL gypsum cements are used for vacuum forming models and molds. Offer high strength, improved heat resistance for prototype, short run and production applications.

NEW EPOXICAL*

NEW EPOXICAL tooling plastics permit laminating or casting of precise, economical epoxy resin patterns and models in half the time required by traditional techniques.

pioneering in ideas for industry

**HYDROCAL and ULTRACAL are trade marks Reg. U.S. Pat. Off. for super strength gypsum cement manufactured by United States Gypsum Company. EPOXICAL is a trade mark for epoxy resins manufactured by United States Gypsum Company.*



Fabricated plastic parts on Boeing B-52's demonstrate Swedlow versatility

Practically everywhere you look in a Boeing B-52D you see plastic parts built by Swedlow . . . parts made of laminated transparent acrylic plastics, nylon, heat-resistant, and fiberglass laminates. The diversity of shapes and sizes is indicated by the items illustrated.

Swedlow offers you highest quality of workmanship – a reliable record of delivery performance – technical expertness in formulating and fabricating.

For complete information on Swedlow services, including new "honeycomb" cores and fabricated parts, we invite your inquiry on your company letterhead.

The Boeing B-52D Stratofortress is an eight-jet, swept-wing, U.S. Air Force long-range heavy bomber now in production by Boeing. Wing span, 185 ft. Overall length, 156 ft. Tail height, 48 ft. Sweepback, 35 deg. Gross weight, over 400,000 lbs. Powered by eight Pratt & Whitney 157 turbojet engines, each rated in the 10,000 lb. thrust class. Boeing-developed "Flying Boom" aerial refueling gives the B-52D virtually unlimited range beyond the specified "more than 6000 miles." Speed, 650 m.p.h. Service ceiling, over 50,000 ft.

POLYESTER REINFORCED FIBERGLASS PANEL SUPPORT

Typical Swedlow Parts on the Boeing B-52D

PANEL SUPPORT

Important Facts About the $12 Billion Packaging Market . . .

PRACTICALLY ALL PRODUCTS are packaged. It's almost easier to count the industries that *don't* package than those which *do*. That's why the packaging market is horizontal . . . includes the thousands of companies that make products of all kinds that are packaged for shipment or sale.

Packaging is, in fact, so integral a part of business as a whole that it expands as business expands. In 1954, according to the U. S. Department of Commerce, the value of materials, supplies and services used in packaging the nation's output stood somewhere between 12 and 15 billion dollars. And as the national output of goods increases each year, so does the demand for packaging, packaging equipment and related supplies.

What the Market Uses . . . and Buys

The range of America's products are as wide as our ingenuity. And the variety of containers is equally broad. Depending on the nature of the product, its package can be a bag, barrel, bottle, box, can, carton, chest, crate, capsule, drum, envelope, jar, tube, vial or wrapper.

Often a package will be a composite of several of these forms and will use many materials: adhesives, coatings, cork, fabric, film, foil, glass, ink, wood, paper, plastics, tape, and wax.

To make these containers—and fill them—takes bag machines, bottling equipment, box machines, capping equipment, cartoners, conveyors, counters, die-cutters, filling machines, labelers, printing presses, scales, slitters, staplers, stitchers, unscramblers and vibrators. And they may also require such additional services as embossing, fabricating, laminating, plastic molding, and contract packaging.

All of these containers, materials, supplies, services and machines are part and parcel of "packaging." They're the factors that give the market its tremendous scope.

Who Does the Buying

The factors that control package selection are as complex as business itself. They include production, quality control, shipping, display, advertising, sales, promotion . . . and, often, outside packaging consultants. The purchase and specifications of packaging materials usually cuts across many departments of a company.

Because the buying influences are so diverse, it is difficult for salesmen to reach them all. Most suppliers, therefore, rely heavily on advertising to carry a good share of their selling lead.

How Modern Packaging Fits In

MODERN PACKAGING is the oldest and largest magazine serving the packaging field. Prior to its founding in September, 1927, the concept of packaging as a common function of many industries was not generally recognized, nor was it realized that these industries have common packaging objectives, techniques, problems and procurement needs.

MODERN PACKAGING changed all that. It gave the users of packaging everywhere a single reliable forum where mutual problems might be solved and where new packaging materials, methods and services could be publicized. As a result it gave packaging suppliers a *single* medium through which they could reach the various buying influences in the many industries that package the great bulk of the nation's goods.

Paid Circulation is Essential

Because of the intricate purchasing patterns involved in the selection and specification of package designs, materials and equipment, it's just not possible to select "packaging men" simply on the basis of job titles.

For this reason MODERN PACKAGING's policy of *paid circulation* is vitally important to advertisers. It is insurance that subscribers are directly and intimately concerned with packaging operations, because packaging men identify themselves and their interests by laying hard cash on the line.

Since the magazine's founding in 1927, its paid circulation has risen steadily—from 2,500 to its current all-time high of 20,600 out of a total print order of 24,500. The bulk of the remaining copies are used to provide additional rotating distribution for conversion into paid subscriptions.

Editorial Content

The editorial purpose of MODERN PACKAGING is to keep packagers informed of all the significant advances in the methods, materials and equipment of the art. Editorial feature space is devoted to carefully researched original articles. About 90% is staff written. 10% contributed by authorities in the field. Through the use of analyses, illustrations, case histories and "how-to-do-it" articles, the editors point out and interpret packaging trends.

Advertising Acceptance

Year after year, *more* advertisers invest *more* money in *more* space in MODERN PACKAGING than in *all other packaging publications* combined. And, last year, they set new all-time highs in both *space* and *dollar volume!*

Get More Facts

To learn more about the sales potentials in the packaging field for the products *you* make, just write to *Advertising Manager,* MODERN PACKAGING, 575 Madison Avenue, New York 22, N. Y.

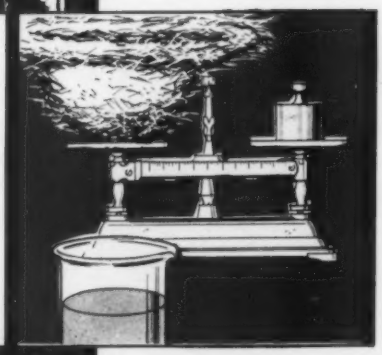
THIS SYMBOL IS YOUR ASSURANCE OF QUALITY FIBER GLASS REINFORCED PLASTICS

Properly-made fiber glass products have unusual strength, light-weight, dielectric strength and high corrosion, heat and weather resistance. All this plus molded-in color, and such optional characteristics as translucency, flexibility and texture.

Fiber glass moldings can often reduce manufacturing costs by replacing a cast or fabricated part. "Fiber glass," with its magic appeal, can enhance the appearance of your product through freedom of design.

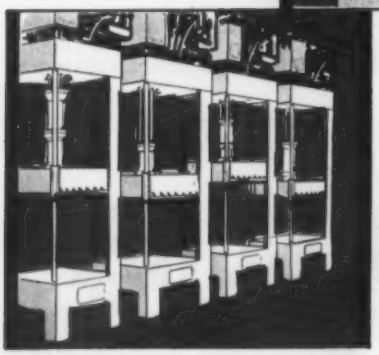
Since 1948, Structurlite has been helping scores of customers capitalize on the advantages of fiber glass molding in a wide range of products from safety hats to school furniture.

Our experience covers all types of resin and fiber applications. We can meet virtually any production requirement, and have facilities for finishing, assembling and packaging.



Throughout, quality is emphasized time and again—from selection of the best resins and fibers, to insistence upon careful workmanship, and a rigid quality control system.

A versatile battery of presses up to 500 ton capacity, automatic preforming machines, other equipment and methods have been designed to maintain the high standards of quality at the lowest possible costs.



We invite an opportunity to discuss with you the application of fiber glass in your product or manufacturing operation. Write for illustrated brochure on significant fiber glass applications, pioneered by Structurlite.

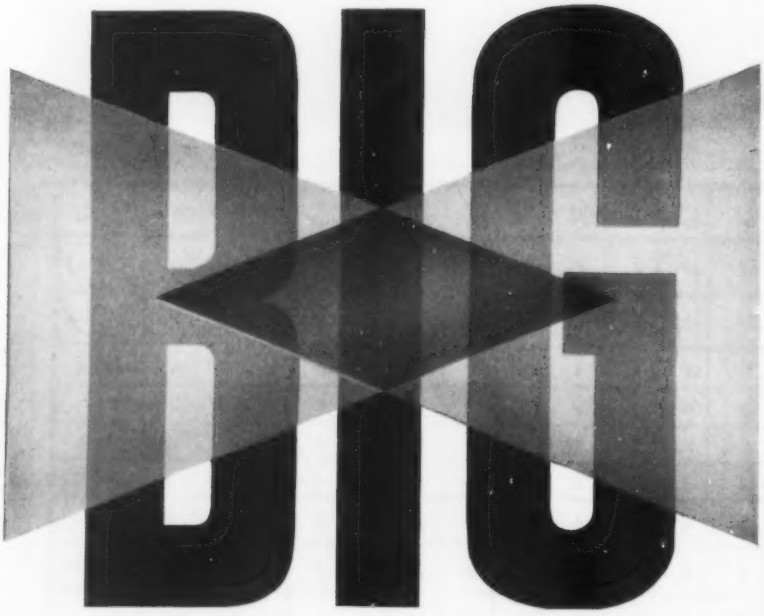
NATIONAL VULCANIZED FIBRE

SHEETS • RODS • TUBES • ROLLS • COILS
FABRICATED PARTS

This low-cost material has excellent mechanical and good dielectric strength, unique arc expulsion properties, excellent machining and forming qualities. It is smooth, durable and light-weight. It is manufactured in many grades and forms with varying degrees of hardness, flexibility, resilience, drawing, forming and punching qualities.

NATIONAL NYLON

EXTRUDED ROD • FABRICATED PARTS



A superior thermoplastic combining good mechanical and electrical properties with excellent chemical resistance. Its strength, low coefficient of friction and resistance to wear and abrasion is outstanding. Material advantages include low tooling costs, design flexibility, close tolerance machining, low cost pilot runs, immediate availability.

OUR PLASTIC SHEETING IS

Specializing in the largest rigid plastic laminated sheeting, Laminations, Inc. is prepared to tailor its BIG sheets to your most exacting specifications.

These big sheets are produced in most any material, especially in vinyl and polyethylene, in pressed polished or matte finishes on both sides or in combination—one side pressed polished, the other side matte. Thicknesses: 5 mils to 1 inch. Sheets have flawless surfaces and require only a minimum of trimming.

In answer to an ever increasing demand, Laminations, Inc., combines quality with bigness.

High and low impact p. v. c. **Sizes: to 54" x 120"**

PRESS POLISHED
sheets for graphic arts applications in sizes to 54" x 120"

EMBOSSED
sheets for structural and decorative uses in sizes to 48" x 144"

LAMINATED
sheets with paper, fabric and other embedments in sizes to 54" x 120"

LAMINATIONS, INC.

1008 S. IRVING AVENUE SCRANTON, PENNSYLVANIA

Quick Quiz

for suppliers of plastics packaging and plastics packaging materials

Q. What's the most effective magazine for advertising to men who buy packaging supplies?

A. Judged by the votes of the men who should know best—the companies and advertising agencies who back their opinions with advertising appropriations—*Modern Packaging* is far and away the most powerful and influential medium. In 1956, *Modern Packaging* carried the advertising of 96% *more* packaging suppliers than the second-place publication!

Q. Which packaging magazine provides the greatest amount of helpful editorial material and how-to-do-it information for its subscribers?

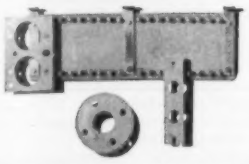
A. *Modern Packaging* routinely carries more than twice as many pages of editorial matter as any of the other publications in the packaging field.

Q. Which packaging magazine presents the greatest volume of advertising?

A. In 1956 *Modern Packaging* carried 2,185 pages of advertising as aganist 1,154 for the second place publication.

Q. Which magazine do buyers of packaging find most useful?

A. At the 1957 National Packaging Exposition sponsored by the American Management Association, an independently conducted survey of exposition visitors showed that *Modern Packaging was voted "most useful" by a 2½-to-1 ratio over the second-ranking periodical.*



If you make anything that packagers buy, you'll want to know more about *Modern Packaging*, as an advertising medium; whom it reaches, how it stimulates buying action, how much is costs to deliver your sales messages in it. Just write to Advertising Department, *Modern Packaging* magazine, 575 Madison Avenue, New York 22, N. Y.

CONTINENTAL-DIAMOND FIBRE

A SUBSIDIARY OF THE Keuffel COMPANY NEWARK 29, DELAWARE

HELPS YOU IMPROVE DESIGN
HELPS YOU SIMPLIFY PURCHASING
HELPS YOU SPEED PRODUCTION

DILECTO LAMINATED PLASTICS

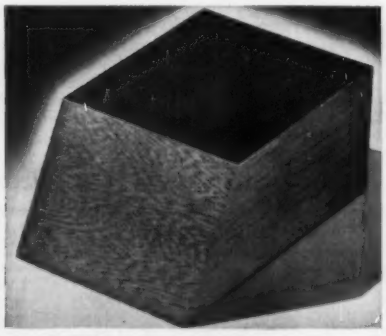
POST-FORMING: Certain Dilecto grades (CF-1, XF, and XF-FR) may be formed to special shapes by heating and placing in an inexpensve cold mold. The thermoelastic properties of these Dilecto laminates open many production and design opportunities. Already widely used by the aircraft and switchgear industries, Post-Forming Dilecto merits full investigation by every alert manufacturer. Write for complete C-D-F engineering service.

DILECTO ROLLED OR MOLDED TUBING finds wide usage in radio and electrical equipment because of excellent insulating and mechanical properties. Impregnated paper or fabric is rolled on a mandrel between heated pressure rolls, then oven baked or press cured in a heated mold to set up the resin.

Dilecto meets the need for a non-metallic lightweight insulating material that is moisture resistant, good electrically, strong and adaptable to all fabricating operations. Some grades have exceptionally high mechanical strength—tensile, flexural, impact; others have flame resistance, high dielectric strength, high insulation resistance, high arc resistance and low loss factor.

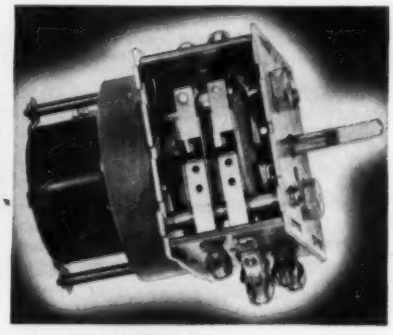
Dilecto is a laminated material made from a base of either cellulosic paper; heavy or fine weave woven cotton fabric or mat; asbestos paper, woven asbestos fabric or mat; woven glass fabric or mat; and is coated with a synthetic resin.

The selection of the proper base material, the proper resin in the correct proportion, is C-D-F's job, but the end user must realize how important it is that he fully understands what dividend results can be gained mechanically, and electrically, and from a cost standpoint, by getting the very best C-D-F material for the project. Here is a brief, yet complete listing of Dilecto sheet grades, each one with a combination of proven characteristics built into the material for the specific job.

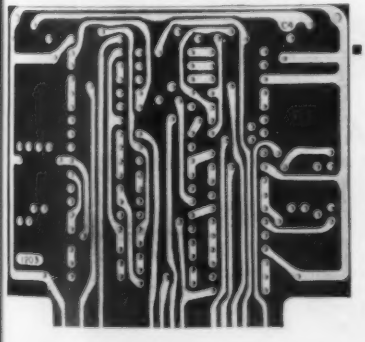


SHEET GRADE CLASSIFICATION (Rod and Tubing similar to sheet stock)

- X For mechanical applications when electrical properties are secondary.
- P For punching (paper-based grades).
- XX For electrical applications requiring mechanical strength.
- XXX For high humidity applications with minimum cold flow.
- L For mechanical applications requiring fine machining.
- C For mechanical applications requiring toughness plus impact strength. For chemical and special uses.
- CE and LE For electrical uses requiring greater toughness than paper-based grades.
- GB For applications requiring heat resistance and high mechanical strength. Supplied in combination with phenolic, silicone, melamine, polyester, epoxy, or Teflon resin.



Note: Various C-D-F grades, identified by numbers affixed to the grade classification, are available. Ask for catalog.



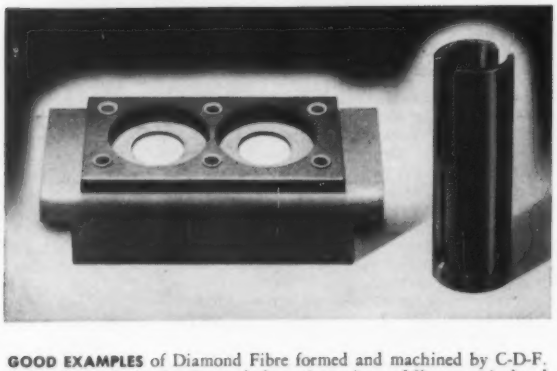
VERSATILE is the word for Dilecto. Sheets, tubes, rods, fabricated specialties can be furnished rapidly at low cost for difficult jobs. Write for new complete Dilecto catalog, and send us your print for quotation.

DILECTO is almost homogeneous and has been made using the latest advances in resin and laminating techniques. It is easily machined, is always uniform in nature . . . a quality basic material with many uses.

A GOOD SWITCH like this relies on dependable electrical insulation. C-D-F sales engineers work with the designer, helping him get the best materials at the lowest cost. Why not call us in on your product problem?

METAL CLADS FOR PRINTED CIRCUITS

The selection of metal-clad stock for printed circuit applications depends often upon the stability and uniformity of the core material. C-D-F offers the designer and production engineer a working range from low-cost phenolic stock to a Teflon glass-based laminate with resistance to extreme temperatures. Also, C-D-F can offer higher and better bond strengths because of improved laminating techniques and the use of the latest bonding methods. For complete specifications, sheet sizes, write for Metal-Clad Folder and samples.



DILECTO Metal-Clads—Most practical grades are Dilecto XXXP-26 and XXXP-28, phenolic paper-based laminates with high moisture-resistance and excellent electrical properties. Also, copper-clad epoxy glass-fabric laminate.

TEFLON Metal-Clads—Glass fiber cloth with Du Pont's Teflon resin. Outstanding resistance to high heat with low dielectric loss properties. Write for samples.

CONTINENTAL DIAMOND FIBRE

. . . C-D-F IS A BIG, RELIABLE SOURCE FOR MANY FABRICATED AND FORMED

VULCANIZED FIBRE

GOOD EXAMPLES of Diamond Fibre formed and machined by C-D-F. Left—An insulating barrier made from three pieces of fibre, punched and formed. Fibre tubing is even used for rivets. Right—A fibre tube which has been smooth-sawed to length, punched twice and countersunk. C-D-F can handle the entire job for you, do it faster and at low cost. This includes selecting and testing the proper grade of fibre, machining and inspection, assembling if needed.

If your job is to select a general-purpose insulating material that is low cost, useful for both electrical and mechanical applications, easy to machine and form, consider the advantages of a unique old-timer—C-D-F's Diamond Vulcanized Fibre.

WHAT IS FIBRE? Vulcanized fibre is made by combining layers of chemically jelled paper. The chemical compound used in gelling the paper is subsequently removed by leaching and the resulting product, after being dried and finished by calendering, is a dense material of partially regenerated cellulose in which the fibrous structure is retained in varying degrees, depending upon the grade of fibre. —NEMA Standard VU 1-1.1

GOOD ELECTRICALLY. Although given a modest insulation rating for resistance to heat (A.I.E.E. Class A with a temperature limit of 221° F.), Diamond Fibre is often used because of its excellent arc resistance and good dielectric strength. It also has desirable deionizing properties and low heat conductivity. Fibre can be combined or surrounded with moisture-resistant laminated plastic.

MANY GRADES AND FORMS. Diamond Fibre sheet and mill grades include Bone, Commerical, and Electrical Insulation (fish paper) NEMA grades. Fibre tubing is normally made only in Bone grade, with rods available in both Bone and Commercial grades. The chart shown outlines the major characteristics of these grades.

C-D-F BONE FIBRE	Hard, stiffest grade. High density. Resists wear, abrasion, has high compressive strength. Good dielectric strength when dry. Super machining qualities. Not recommended for bending.
C-D-F COMMERCIAL FIBRE	Mechanical and electrical grade. Medium density. Tough, pliable. Good mechanical properties. Fair dielectric strength, normally high when dry. Can be bent, punched, and formed.
C-D-F DIAMOND INSULATION	Electrical insulation "fish paper" grade. Unusually free from foreign matter. Withstands extreme bending and forming without cracking. High dielectric strength, except under high humidity.

TOUGH, RESILIENT, STRONG. How long has it been since you examined the unique properties and wide range of C-D-F fibre grades? Vulcanized Fibre is arc resistant, mechanically strong, non-corroding, half the weight of aluminum. Repeated moistening and drying in forming insignificantly alters the nature, structure or quality of the fibre.

A BIG, RELIABLE SOURCE. C-D-F does business with the largest tonnage users of sheet, rod and tube fibre in the world. This means good deliveries, good prices, reliable products for every new customer. You deal with a materials engineer, a C-D-F man who knows how to give you the most value in Diamond Vulcanized Fibre. If you want to improve design, simplify purchasing, speed production, use Diamond Fibre and the facilities of C-D-F. Write for new Diamond Fibre catalog and free test samples, or send us your print for quotation.

MECHANICAL PROPERTIES OF DIAMOND VULCANIZED FIBRE

Property	Sheet thickness, tube wall or rod diameter	SHEETS Bone CW	SHEETS Bone LW	SHEETS Commercial CW	SHEETS Commercial LW	TUBES	RODS Bone	RODS Commercial
Tensile Strength	Up to 1/8"	6500	8500	6000	8000	6500	8500	8000
	Over 1/8 to 1/2	6000	8000	5500	7500	6500	8000	7500
	Over 1/2	....	....	5000	7000	6500	....	7000

	Over 1/8 to 1/4					9000		
	All thicknesses or diameters	30,000		20,000			8000	6,000

NOTE—* Tensile strength only.

VULCOID — RESIN-IMPREGNATED FIBRE

Only C-D-F supplies Vulcoid in sheets, tubes, rods, and fabricated parts. Made from Diamond Vulcanized Fibre that has been uniformly impregnated with a special resin, Vulcoid is a material approved and identified by the Underwriters' Laboratories as Class A Insulation. Natural greenish-tan in color, it is economical, easy to machine and punch. Property-wise, Vulcoid is an intermediate grade between Commerical Fibre and XX phenolic Dilecto.

USES: (requiring arc resistance and mechanical strength)—contact and connector panels, knife switch arms and guides, arc deflector spacer bushings; (requiring dielectric strength and moisture resistance)—electrical fixture insulation, wiring devices, plugs, receptacles; (requiring moisture and arc resistance)—motor and transformer lead bushings and terminal blocks. Write for folder V-55, and test samples.

CONTINENTAL DIAMOND FIBRE

MODERN PLASTICS THAT HELP INDUSTRIES SAVE MONEY!

TEFLON — HIGH HEAT INSULATION

OUTSTANDING PROPERTIES

HEAT RESISTANCE: Due to the non-flammability and high heat resistance of Teflon,* it easily meets both Class B and Class H, AIEE standards for maximum hot spot insulation temperature. Teflon-coated glass fabric laminates withstand 250° C. continuously and up to 300° C. intermittently. One factor which influences the heat resistance of Teflon is that there is no apparent degradation from oxygen, which has a definite degrading effect on silicone materials.

*Du Pont Trademark

MOISTURE RESISTANCE: A Teflon laminate has practically zero water absorption and its electrical properties are little affected after long exposure to high humidity. Teflon is unaffected by fungus and temperature changes. Not only has it lower moisture absorption than any other laminate known, but it tends to repel water . . . retaining high surface insulation resistance properties even under extreme humidity conditions.

FORMS: C-D-F molds, machines and processes Teflon into the forms you need . . . *unsupported* or pure Teflon sheets and tapes, glass-fiber cloth *supported* sheets and tapes, metal clad stock for printed circuits, diaphragm sheet stock, gaskets, packing, release materials, tubes and rods.

NEW CEMENTABLE TEFLON: CDF now offers unsupported and glass-supported Teflon in sheets and tapes with the added advantage of being readily cementable to itself or to other materials with commercial adhesives. Treated usually on one side only, the Teflon retains its unique mechanical and electrical properties on the untreated side and modifies the treated side to a surface that accepts adhesives and bonds readily. Write for full technical data.

DIELECTRIC STRENGTH: The dissipation factor and dielectric constant of Teflon laminates are both extremely low over a wide frequency range. From 60 to 100 megacycles. the dissipation factor range is between .005 and .0005, and the dielectric constant ranges from 2.8 to 2.5 when measured in a field perpendicular to laminations. As corona will slightly degrade Teflon, care should be taken in designing parts used at voltages over 2500. Sharp corners and other contributing factors to corona should be avoided.

CHEMICAL INERTNESS: Resistant to hot corrosive salts and most concentrated acids. Pure Teflon is unaffected by all known chemical agents, excepting molten alkali metals and, under special conditions, fluorine and chlorine trifluoride. Glass-supported Teflon, when exposed at cut edges, is affected only by those chemicals which attack glass. Otherwise, its properties remain the same.

Write now for Technical Folder. Call your C-D-F sales engineer who will explain C-D-F's technical and production facilities for providing you with Teflon . . . industry's most promising plastic!

SPIRAL TUBING

GOOD DIELECTRIC STRENGTH
LOW DIELECTRIC LOSS PROPERTIES
GOOD MECHANICAL STRENGTH AND MOISTURE RESISTANCE

C-D-F is a dependable source of supply for all of your coil form spiral tubing needs. Uniform high product quality is maintained by rigid standards of manufacture. C-D-F offers you fabricating skill, backed by exacting technical and inspection control. A recent C-D-F development is Grade 5 Constant Torque Tubing for use in coil forms. After the threaded iron tuning core is inserted and finally adjusted, you obtain the same stable torque rating. Constant Torque features: exact internal threading . . . every thread engaged. 3-point contact with core prevents binding and permits positive tuning and re-tuning. Outer surface of tube has no weak spots, no external embossing to cause cement leakage. Available in lengths up to 14" to take .248" to .250" core with 28 threads per inch and also 6-32, 8-32 and 10-32 screw sizes. Write for samples. Grade 5 Tubing is also custom-fabricated by C-D-F in conventional shapes to accommodate other sizes of tuning cores. C-D-F produces spiral tubing in grades to meet most requirements. Use the Grade Selector Chart when requesting samples and additional information. Write for folder.

MICABOND

C-D-F has special know-how, extensive plant for producing superior mica insulation. Only the finest mica splittings are used; coverage is completely leak-proof with improved strong binders used. America's largest users of mica products rely on C-D-F for uniform, high-quality Micabond tapes, sheets, segments, tubing, "V" rings, slot liners. To build a better motor, to get more insulation value, specify Micabond. Write for new Micabond catalog M-55, samples, technical aid.

CONTINENTAL DIAMOND FIBRE

PLASTICS FOR EVERY PURPOSE FROM ONE BIG SOURCE

FLEXIBLE INSULATION

THREE HIGH-HEAT TAPES

C-D-F SILICONE TAPES for AIEE Class H Electrical Insulation. Available in varnished glass-fiber cloth and silicone rubber-coated glass-fiber cloth. Resistant to high temperatures. High dielectric strength. Write for Technical Bulletins #47 and #52 and new Flexible Insulation catalog.

C-D-F TAPES OF TEFLON* withstand 500°F. Practically zero water absorption. Sold in 100% Teflon film or Teflon glass-fabric-supported. Used for wrapping field coils, wrapping cables subject to abrasion of undertar blast. Write for Folder and samples. New *cementable* tapes of Teflon (see previous page for details) make the use of flexible insulations of Teflon even easier.

C-D-F MICABOND TAPES are used for insulating motor and generator armature and field coils. Flexible. Wide range of sizes and backings. Write for new Micabond Catalog. Call the C-D-F sales engineer listed below—he's a good man to know!

*Du Pont trademark

CELORON

MOLDED INDUSTRIAL PLASTICS

Celoron of laminated or molded-macerated cotton fabric-base construction is used extensively for industrial and automotive timing gears. Celoron molded-macerated cotton fabric or paper is used for many mechanical and structural electrical applications. Celoron is unaffected by rapid temperature changes, may be used continuously at 225 to 250°F. It has high impact strength, excellent resistance to heat, oil and water, many chemicals. Both laminated or molded Celoron is easily machined.

SHEETS

From laminated stock, fabric-based phenolic-impregnated Celoron can be furnished in sheets, cut pieces, blanks and rings machined from sheet stock. For gear applications (idler and spur gears, and cams), it is normally identified by two black lines. See Dilecto C grades for mechanical applications requiring toughness plus impact strength.

MOLDED

Celoron can be molded to close tolerances for both mechanical and electrical applications. Rugged, dimensionally stable, readily machined, Celoron is a dependable material; remember C-D-F has both the men and equipment to handle "big run" molding requirements.

Colors: Golden mottled brown or black.

GEARS

These gears, pulleys and discs are all Celoron which finds wide usage in textile and printing machinery. Build silence into your product with Celoron gears. Write for Celoron catalog with horsepower ratings.

INSULATION

This diesel contact controller drum assembly uses two C-D-F products: Celoron drum body, drilled and broached, Diamond Vulcanized Fibre between fingers of the brass contact plate.

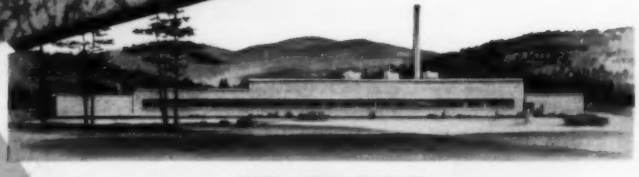
A SUBSIDIARY OF THE Bird COMPANY NEWARK 29, DELAWARE

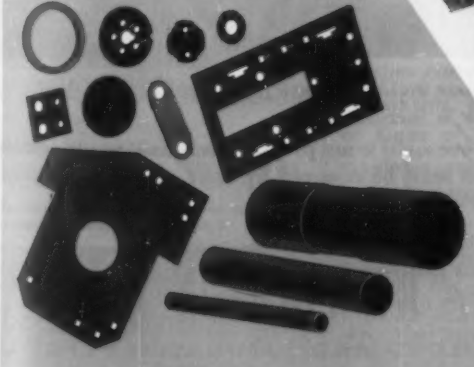
New IMPROVED PAPERS *for* DECORATIVE *and* INDUSTRIAL LAMINATES

Constant research and evolution now enable us to produce new and improved papers for decorative laminates. These new offerings to the laminating industry include:

1. **Lighter Weight Print Base Papers** having the same range of opacity as the earlier types. Very worthwhile savings accrue through the use of these high opacity lighter base weight papers.



You save paper cost
save resin cost
save freight cost
save storage space



In addition laminates with less tendency to warp are possible.

2. **Improved white overlays**

3. **Metallic inclusions** in transparent overlay for sparkle effect.

Samples on request.

OUR NEW PLANT
Now under construction will double our present production capacity.

HURLBUT
PAPER COMPANY
SOUTH LEE, MASSACHUSETTS

... better molded parts because of

1200 years of tool and die experience

At least 50% of getting a good molded part depends on the quality of your mold.

One hundred Richardson men have more than 1,200 years combined experience in the design and production of tools and dies for the production of molded plastic parts. They provide the broad and varied experience needed for the design and production of quality molds to close tolerances.

The men who make Richardson molds know and respect the many "ifs" encountered in the design and production of quality molds. They know that . . .

. . . if your mold isn't correctly designed, the resulting parts will not be according to specifications.

. . . if your mold is not properly designed, the parts cannot be ejected quickly, production speed will be reduced, and unit cost increased.

The Richardson mold and die shop at Melrose Park, Illinois, is one of the largest in the plastics industry.

. . . if your mold walls are not of uniform thickness, curing time is increased.

. . . if your mold is not properly designed, resulting excessive flash must be removed by hand . . . a costly procedure.

Richardson engineers can assist your engineers in (1) redesigning parts for conversion from other materials to molded plastics, and (2) designing to improve molded parts now in production.

For additional information and a copy of the newly published catalog, "Richardson Molded Plastics," write or phone, today . . . Chicago number, MAnsfield 6-8900.

Parkwood

high-pressure laminates

Manufacturing under the highest pressures that it is desirable to use, Parkwood adheres to meticulous laboratory controls and production techniques; meets or exceeds the highest standards of the industry.

INDUSTRIAL LAMINATES

HI-DEN (Parkwood's trade name for densified wood) — a laminate of carefully selected birch veneers, impregnated with phenolic resins. Hi-Den is a homogeneous material of extreme density, strength, moisture resistance and dimensional stability.

Available in several grades, in panels up to 2" thick and varying widths and lengths, Hi-Den can be machined to close tolerances with high-speed woodworking tools, belt or disc sanders and buffed to a high polish.

Used successfully for picker sticks, strain insulators, power sticks, forming and drawing dies for light metal, its beautiful natural wood grain has also made it a favorite material for cutlery and other handles, clarinets, store fixtures, architectural hardware, etc.

Our engineers will be glad to work with you on specific problems. For illustrated Hi-Den brochure, price list, etc., write Dept. H.

PARKWOOD 8000 — a kraft paper impregnated laminate of great density and stability. Especially recommended for flat thin applications such as bench tops or routing templates, fixtures and some types of Hydro-form dies.

DECORATIVE LAMINATES

for Duty, for Beauty

Parkwood decorative panels offer architects, designers and fabricators maximum quality, range, flexibility and long-run economy. Protected for life by genuine Melamine — unsurpassed for appearance, feel, and resistance to abrasion.

DECORATIVE Parkwood does the top styling job of the industry in this group, with many smart patterns and the finest and largest selection of plain colors available anywhere.

GENUWOOD High-pressure laminate incorporating a layer of *genuine* precious-wood veneer — the ultimate in surfacing for fine furniture, bars, counters, store fixtures.

ROTOWOOD Authentic reproductions of beautiful natural wood grain brought to a high degree of perfection by Parkwood's years of experience with wood veneers.

SUPERWOOD A premium Rotowood featuring exclusive multi-color reproduction of selected wood grains at a slight advance in price.

For handsomely illustrated brochure, samples, and name of nearest distributor, write Dept. D.

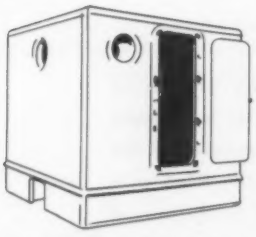
How to figure your sales potential in the plastics field

FREE . . . 40-page brochure will help you find answers to your questions about sales opportunities in the fast-growing plastics field.

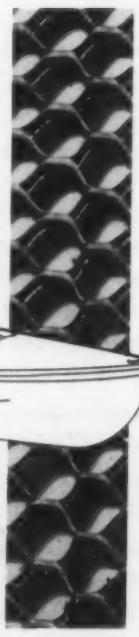
THIS NEW STUDY contains the inside story of one of America's fastest growing industrial markets. It presents one of the most stimulating and detailed analyses of the plastics field that has yet been published. It's filled with up-to-date figures on the consumption and production of plastics materials, on the field's processing equipment requirements, on potential areas of growth. It lists hundreds of kinds of machines, accessories, chemicals and intermediates, supplies and special services for which the field is manifesting an ever-increasing appetite.



You will find this handsome brochure—file size, lavishly illustrated, 40-pages—a valuable addition to your business library. It may well point the way to increased sales for the industrial products or services that your firm supplies.

For your free copy of "The Plastics Field," simply address a note on your company letterhead to *Advertising Manager*, Modern Plastics, 575 Madison Avenue, New York 22.

AIRCOMB *may be your solution, too!*



TRADE MARK

AIRCOMB SEA CABIN

AIRCOMB-HULLED BOAT

DOUGLAS

The high standards set for the "Monsanto House of the Future" made the selection of the finest materials imperative. Douglas AIRCOMB – a phenolic Kraft honeycomb structure – was chosen as a primary structural element. Its great strength, rigidity and outstanding insulation properties made it ideal for use in ceilings, floors, interior partitions and sliding doors.

It will be worth the while of every plastics engineer and manufacturer to get the facts on this exceptional material. Small boat designers have been particularly interested in AIRCOMB's high strength to weight relationship and resistance to corrosion and have been using it extensively for hulls, decks and cabins.

Faced with glass laminates or plastics, AIRCOMB is potentially useful wherever the combination of high strength and light weight is desirable. It is guaranteed by Douglas to have uniform strength and rigidity.

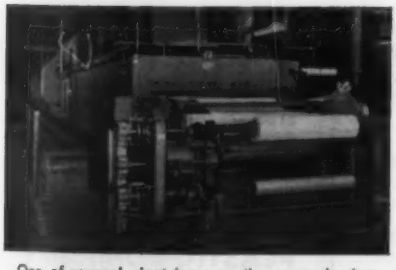
- **MELAMINE IMPREGNATED PAPERS** in a wide variety of patterns, wood grains, solid colors, and translucent overlay grades for durable decorative laminates. Available in rolls slit to width, sheeted, or die-cut to any shape required.

- **PHENOLIC IMPREGNATED PAPERS** for producing N.E.M.A. industrial grade laminates and molded parts for a wide range of electrical, mechanical, and structural applications. Precisely controlled processing assures uniformity of quality.

- **PHENOLIC IMPREGNATED FABRICS** such as cotton duck, cloth, and sheeting for high or low pressure molding. Available in grades to meet N.E.M.A. standards. Also used in producing gears, bearings, filters, helmets, and many other products.

FABRICON

PLASTIC IMPREGNATED MATERIALS



for Molding and Laminating

- **PHENOLIC IMPREGNATED GLASS CLOTH** produced in special grades for fabrication of fly rods, aircraft and guided missile parts, plus many other products requiring a strong, light, durable material highly resistant to heat and corrosion.

- **POLYESTER IMPREGNATED MATERIALS** such as glass fabric and mat for low pressure molding of aircraft parts, tools, and other applications where high strength, light weight, ease of forming, and dimensional stability are essential properties.

- **SILICONE IMPREGNATED GLASS CLOTH** in grades having excellent dielectric strength and resistance to distortion at high temperatures, plus other properties required for applications such as radar equipment, printed circuits, motors, etc.

- **EPOXY IMPREGNATED MATERIALS** custom treated to meet the highly specialized requirements of many electrical and electronic devices used for an ever-increasing number of military and industrial applications.

One of several giant impregnating ovens having roll capacities up to 90" in width. All are designed for continuous quality controlled operation.

Whenever you need plastic impregnated and coated materials, you'll do well *always* to think of Fabricon *first!* For regardless of what your requirements may be, you'll find that Fabricon has what it takes to deliver the quality and service that you've been looking for. Years of experience with all types of thermosetting resins and fillers. Complete engineering and laboratory facilities for developing new products and processes. Special production equipment designed for precisely controlled, continuous, economical operation. Facilities, too, for slitting material to width, sheeting, or die-cutting to any shape required.

Want detailed information on the Fabricon Plastic Impregnated Material that's *right* for your particular product? Just outline the nature of your application and send it in today!

WHY *Decarlite* IS THE FIRST CHOICE

high pressure decorative laminate

Fabricated in one of America's newest and most modern plants. Every operation skilfully controlled to produce the very finest laminates. Available in Four Basic Types

DECARLITE —The modern decorative plastic sheet laminate for surfacing dinettes, counters, bars, sink tops, furniture, school desks—wherever a durable, decorative surface is required. In many decorative designs and colors, including exclusive new wood-grains. Available in GLOSS or DULL RUBBED finish.

DECAFORM —Decorative DECARLITE in postforming grade. Can be formed to inside, or outside, contours by application of heat and forming pressure.

DECAFLEX —Decorative DECARLITE in a low caliper, formable grade for applications where bending at room temperature is required.

SUPER-DECABOARD—Decorative surfaced hardboard for applications requiring a rigid type panel such as occasional furniture, headboards, display panels, etc.

it's nelco for "Know-How"

PLASTIC LAMINATES

In the production of *consistently*-high quality industrial-grade laminates for the electrical and electronics industries, Nelco's Know-How makes the finest possible use of unrivalled facilities for Research, Development, Production and Quality Control.

Unclad, or metal-clad on one or both sides, NELCO Laminates in thicknesses of 0.005" up—in sheets 36"x48", 36"x60", or 36"x72"—predictably meet the highest standards of the printed-circuit industry.

NELCO 100® and EPOGLAS® Epoxy-Glass-Cloth Laminates: for high strength, excellent dimensional stability and wet electrical-insulation properties, in electronic and printed-circuit applications.

NELCO 130 Epoxy-Paper Laminate: for excellent punchability and superior dimensional stability; no adverse effects from vapor degreasing.

NELCO 230 XXXP Phenolic-Paper Laminate: for superior cold-punching properties; especially well suited to printed-circuit applications in automated assembly.

POLYGON

Polyester and Epoxy EXTRUSIONS

RODS
1/16" to 4½" diam.

TUBES
1/16" to 1" i.d.

SHAPES
Squares, rectangles, hexagons, channels, etc.

Polygon extrusions are produced by a patented continuous process* which assures equal and continuous distribution of the tough reinforcing glass filaments and resin in each extrusion.

- tremendous strength
- excellent electrical properties
- controlled flexibility
- hardness
- low water absorption
- complete corrosion resistance

Polygon serves the electrical industry with many proven applications such as coil forms, motor wedges, spacers, selenium rectifiers, brush holders, relays, controls, strain bar insulators and many other uses.

Extrusions available in precision cut lengths or machined to specification.

Color O.K.!

The paper machine seen at the right is ready to run a large quantity of saturating paper for a leading manufacturer of laminated plastics. However, production won't start until a sample of the paper has been laminated in the Wrenn laboratory, to make certain that the color of the finished product will match the laminator's standard.

Leading laminators rely on WRENN for uniform quality and accurate color matching in SATURATING PAPERS

A modern, air-conditioned laboratory in the Wrenn mill is at the service of laminators who wish to write their own specifications for saturating and other absorbent paper. Technicians work in three shifts to develop products that will meet specified standards and to maintain quality control at every stage of production.

While color matching is of extreme importance in making saturating papers for decorative applications, it is only one of the many phases of quality control in the Wrenn mill. Other physical characteristics, such as basis weight, caliper, Mullen, density and absorbency, are carefully checked and must comply with accepted standards.

Samples of Wrenn saturating papers, for both decorative and industrial applications, will be gladly submitted on request.

THE WRENN PAPER COMPANY

Plaskon®

INDUSTRIAL RESINS . . . leaders in the field

Polyester resins for laminates

When reinforced with glass fibers, PLASKON Polyester Resins form high strength laminates that are lightweight, corrosive resistant, exceptionally versatile. Product advantages: high impact strength . . . hard, durable surface . . . molded-in color . . . dimensional stability. Rigid, resilient, and flexible formulations to meet specific end-product requirements.

Typical applications: Translucent panels, car bodies, modern furniture, safety helmets, luggage, boat hulls.

Polyester resins for pre-mix moldings

Specially formulated for low-cost pre-mix molding that permits rapid molding of parts with varying thicknesses, intricate contours and molded-in inserts.

Typical applications: Automotive heater housings, door liners and window frames, and ducts.

Adhesives

A *versatile* line including urea powder glue, urea liquid glue and hardeners for all types of gluing including hot and cold pressing, high frequency operations, veneer splicing, edge banding and lumber core gluing. Individual PLASKON Adhesives provide special properties such as ease of application and bonds that have a high degree of moisture resistance, and are non-staining and durable.

Typical applications: Hardwood plywoods, furniture, pianos, radio and TV cabinets, boats.

Phenolic laminating varnishes

Used in core stock for decorative laminates and in the preparation of industrial and general purpose laminates. Exceptional durability.

Typical applications: Kitchen and bathroom counter tops, furniture tops, bushings, electrical insulation, mechanical parts.

Urea resins

PLASKON Urea Resins for paper-treating provide great wet strength and improved folding endurance and dry strength.

Typical applications: All type paper products.

Polyester resins for polyurethane foams

Both rigid and flexible foams can be produced by using PLASKON Polyester Resins in conjunction with diisocyanates such as National Aniline Division's "Nacconate" diisocyanates. Foams are extremely strong and durable, rot-proof, non-toxic, odorless. They can be foamed in place for sandwich construction or in inexpensive molds on a batch basis or on a continuous machine for large sections.

Typical applications: Marine flotation chambers, refrigerator insulation, shoe innersoles, furniture padding and mattresses, sound and thermal insulation, rug underlays.

Foundry resins

PLASKON Foundry Resins include phenolic resins which produce highly permeable shell molds with excellent dimensional stability and smooth surfaces and result in precision castings. Urea, phenolic and alkyd resin types are used in both ferrous and non-ferrous metal castings for binding quick-baking, high-density cores.

Typical applications: Aluminum and magnesium sand castings, ferrous castings.

Yours for the asking!

The companies that supply the equipment, resins, chemicals, molding compounds and services used in the manufacture of plastics products turn out a continuing stream of valuable and informative bulletins, catalogs, manuals, and technical reports. Much of this material is offered without charge to interested businessmen.

You'll find brief descriptions of about four dozen pieces of such literature on the Manufacturers' Literature Page of each monthly issue of *Modern Plastics* magazine . . . and on the same page you'll find a detachable prepaid postcard on which you can order the specific items you want—*free.*

Next issue you get, turn to the Manufacturers' Literature Page . . . and use it!

TABLE I: Synthetic Plastics and Resin Production, Dry Basis[a] (U. S. Tariff Commission)

Material	1955	1956
	1000 lb.	1000 lb.
CELLULOSE PLASTICS:		
Cellulose acetate and mixed ester, total	134,018	136,067
Sheets, under 0.003 gage	18,801	19,384
Sheets, 0.003 gage and over	15,855	16,656
All other sheets, rods, and tubes	7,646	7,282
Molding and extrusion materials	91,716	92,745
Nitrocellulose sheets, rods, and tubes	4,869	5,254
Other cellulose plastics	5,869	5,651
Total	144,756	146,972
PHENOLIC AND OTHER TAR ACID RESINS:		
Molding materials	220,276	214,729
Bonding and adhesive resins for:		
Laminating (except plywood)	82,215	62,832
Coated and bonded abrasives	15,763	15,644
Friction materials (brake linings, clutch facings, etc.)	25,502	b
Thermal insulation (rockwool, fibrous glass)	52,980	56,151
Plywood	44,533	44,187
All other bonding and adhesive uses	27,929	49,789
Protective coating resins, unmodified and modified, except by rosin	28,501	29,503
Resins for all other uses	37,778	39,455
Total	535,477	512,290
UREA AND MELAMINE RESINS:		
Textile-treating and textile-coating resins	47,883	40,784
Paper-treating and paper-coating resins	23,378	24,775
Bonding and adhesive resins for:		
Plywood	99,508	102,081
All other bonding and adhesive uses, including laminating	28,491	25,205
Protective coating resins, straight and modified	38,905	37,250
Resins for all other uses, including molding	90,215	87,167
Total	328,380	317,262
POLYESTER RESINS	61,544	72,588
STYRENE RESINS:		
Molding materials	423,208	433,037
Protective coating resins, straight and modified[c]	103,128	91,135
Resins for all other uses	92,864	104,416
Total	619,200	628,588
POLYETHYLENE	402,279	556,919

Material	1955	1956
	1000 lb.	1000 lb.
VINYL AND VINYL COPOLYMER RESINS[d] (resin content):		
Polyvinyl chloride and copolymer resins (50% or more PVC) for:		
Film (under 0.010 gage)	83,043	78,064
Sheeting (0.010 gage and over)	50,758	52,505
Molding and extrusion	183,131	203,812
Textile- and paper-treating and coating	63,780	62,931
Flooring	55,810	65,500
Protective coatings	26,315	28,522
All other uses	57,509	74,621
All other vinyl resins for:		
Adhesives	35,634	36,563
All other uses	108,503	115,075
Total	703,260	752,410
ALKYD RESINS:		
For protective coatings:		
Phthalic anhydride types:		
Unmodified	325,516	270,375
Modified	129,031	70,977
Polybasic acid types:		
Unmodified	25,597	3,931
Modified	11,469	11,710
For all other uses	6,164	16,049
Total	497,777	373,042
ROSIN MODIFICATIONS:		
Rosin esters for protective coatings:		
Unmodified (ester gums)	40,510	29,562
Modified (hard resins)	63,378	59,299
All other modifications for protective coatings and other uses	30,531	41,331
Total	134,419	130,192
COUMARONE-INDENE AND PETROLEUM POLYMER RESINS	292,574	245,586
MISCELLANEOUS SYNTHETIC PLASTICS AND RESINS:[e]		
Molding materials	51,629	43,542
Protective coating resins	22,691	11,448
Resins for all other uses	89,017	117,894
Total	163,337	172,884
GRAND TOTAL	3,883,003	3,908,734

[a] "Dry basis" is defined as the total weight of the material, *including* resin, plasticizers, fillers, extenders, colors, and stabilizers, and *excluding* the weight of water, solvents, and other liquid diluents.

[b] Included with "All other bonding and adhesive uses."

[c] Includes data for styrene-alkyd polyester resins.

[d] Statistics by use are based on sales; total is based on production.

[e] Includes data for acrylic, epichlorohydrin, polyamide (nylon), polyethylene, silicone, and other synthetic plastics and resin materials.

LIST OF MANUFACTURERS OF FOAMED PLASTICS

1. American Collo Corp., 525-535 Oritan Ave., Ridgefield, N. J.
2. American Latex Products, Inc., 3341 W. El Segundo Blvd., Hawthorne, Calif.
3. American Rubber Products Corp., La Porte, Ind.
4. Atlas Mineral Products Co., Mertztown, Pa.
5. Balsa Ecuador Lumber Corp., 500 Fifth Ave., New York 36, N. Y.
6. Bradley and Vrooman Co., 2629 S. Dearborn St., Chicago 16, Ill.
7. Brown Rubber Co., Inc., Lafayette, Ind.
8. Burkart Manufacturing Co., F., Div. of Textron Inc., 4900 N. Second St., St. Louis 7, Mo.
9. Burnett and Co., Inc., W. T., Baltimore, Md.
10. Chemical Products Corp., King Philip Rd., E. Providence 14, R. I.
11. Colton Chemical Co., 1747 Chester Ave., Cleveland 14, Ohio
12. Crest Chemical Industries Corp., 72 Delavan St., Brooklyn 31, N. Y.
13. Curtiss-Wright Corp., Carlstadt, N. J.
14. Dayton Rubber Co., Dayton, Ohio
15. Dennis Chemical Co., 2701 Papin St., St. Louis 3, Mo.
16. Dow Chemical Co., The, Midland, Mich.
17. Dow Corning Corp., Midland, Mich.
18. Dryden Rubber Div., Sheller Manufacturing Corp., 1014 S. Kildare Ave., Chicago 24, Ill.
19. Dunlop Tire and Rubber Co., Buffalo, N. Y.
20. Dura-Flex Co., 2043 Colorado Ave., Santa Monica, Calif.
21. Elastomer Chemical Corp., 212 Wright St., Newark 5, N. J.
22. Emerson and Cuming, Inc., 869 Washington St., Canton, Mass.
23. Federal Industries, Div. of Textron Inc., Belleville 9, N. J.
24. Firestone Industrial Products Co., Div. of the Firestone Tire and Rubber Co., Fall River, Mass.
25. Flexible Products Co., P. O. Box 306, Marietta, Ga.
26. Foam King, Inc., 1816 Boston Rd., Bronx 60, N. Y.
27. General Electric Co., Pittsfield, Mass.
28. General Tire and Rubber Co., Bolta Products Div., Lawrence, Mass.
29. General Tire and Rubber Co., Industrial Products Div., Marion, Ind.
30. B. F. Goodrich Co., Akron 8, Ohio
31. B. F. Goodrich Sponge Products, Shelton, Conn.
32. Goodyear Tire and Rubber Co., 1210 Massillon Rd., Akron 15, Ohio
33. Great American Industries, Inc., Rubatex Div., Bedford, Va.
34. Hewitt-Robins, Inc., Buffalo, N. Y.
35. Hood Sponge Rubber Co., 340 W. Huron St., Chicago 10, Ill.
36. Hudson Foam Products, Saw Mill River Rd. & Lake Ave., Yonkers, N. Y.
37. Interchemical Corp., Finishes Div., P. O. Box 659, Newark 1, N. J.
38. Isocyanate Products, Inc., P. O. Box 1681, Wilmington, Del.
39. Koppers Co., Inc., Chemical Division, Pittsburgh 19, Pa.
40. Lebec Chemical Corp., 14066 S. Garfield Ave., Paramount, Calif.
41. Loven Chemical of Calif., Newhall, Calif.
42. Magic Chemical Co., 100 Crescent St., Brockton 2, Mass.
43. Marblette Corp., 37-21 30th St., Long Island City 1, N. Y.
44. Minnesota Mining and Mfg. Co., 411 Piquette Ave., Detroit 2, Mich.
45. Mobay Chemical Co., 1700 S. Second St., St. Louis 4, Mo.
46. Mono-Sol Corp., 407 County Line Road, Gary, Ind.
47. Naugatuck Chemical, Div. of U. S. Rubber Co., Naugatuck, Conn.
48. Nopco Chemical Co., Plastics Div., 175 Schuyler Ave., N. Arlington, N. J.
49. Pelron Corp., 7847 W. 47th St., Lyons, Ill.
50. Pittsburgh Plate Glass Co., Paint Div., 1 Gateway Center, Pittsburgh 22, Pa.
51. Poly Resins, 11661 Wicks St., Sun Valley, Calif.
52. Reichhold Chemicals, Inc., RCI Building, White Plains, N. Y.
53. Reynolds Chemical Products Co., 1200 N. Main St., Ann Arbor, Mich.
54. Rezolin, Inc., 5736 W. 96th St., Los Angeles 45, Calif.
55. Robinson Foams Ltd., 183 George St., Toronto, Canada
56. Robinson Moulded Products Ltd., 183 George St., Toronto, Ontario, Can.
57. Rubber Corp. of America, New South Rd., Hicksville, N. Y.
58. Schwab Plastics Corp., 730 S. Dix, Detroit 17, Mich.
59. Sheller Manufacturing Corp., Portland, Ind.
60. Stanley Chemical Co., E. Berlin, Conn.
61. Strux Corp., 37 W. John St., Hicksville, N. Y.
62. Styrene Products Ltd., 96 Piccadilly, London, W. 1, England
63. Trostel and Sons Co., Inc., Albert, Milwaukee, Wis.
64. U. S. Rubber Co., Mishawaka, Ind.
65. Watson-Standard Co., 225 Galveston Ave., Pittsburgh 30, Pa.
66. Westlake Plastics Co., Lenni Mills, Pa.
67. Witco Chemical Co., 122 E. 42nd St., New York 17, N. Y.

LIST OF MANUFACTURERS AND PROCESSORS OF FILMS*

1. Allied Resinous Products, Inc., 525 W. Adams St., Conneaut, Ohio
2. American Lucoflex, Inc., 500 5th Ave., New York 36, N.Y.
3. American Products Mfg. Co., 8127 Oleander St., New Orleans 18, La. (0.5 to 3 mils)
4. American Viscose Corp., Film Div., 1617 Pennsylvania Blvd., Philadelphia 3, Pa.
5. Amos Packaging, Div. of Amos-Thompson Corp., Edinburg, Ind.
6. Associated Rubber and Plastic Corp., 2780 Park Ave., New York 51, N.Y.
7. Bakelite Co., Div. of Union Carbide Corp., 30 E. 42nd St., New York 17, N.Y.
8. Bishop Manufacturing Corp., 10 Canfield Rd., Cedar Grove, N.J.
9. Bolta Products, Div. of The General Tire and Rubber Co., Lawrence, Mass.
10. Borden Co., The, Chemical Div., Resinite Dept., Santa Barbara, Calif.
11. Cadillac Plastic and Chemical Co., 15111 Second Ave., Detroit 3, Mich.
12. Campco Div., Chicago Molded Products Corp., 1020 N. Kolmar Ave., Chicago 51, Ill.
13. Celanese Corp. of America, 290 Ferry St., Newark 5, N.J.
14. Chester Packaging Products Corp., 684 Nepperhan Ave., Yonkers, N.Y.
15. Chippewa Plastics, Inc., Chippewa Falls, Wis.
16. Clopay Corp., Film Products Div., Clopay Sq., Cincinnati 14, Ohio
17. Columbus Coated Fabrics Corp., 7th and Grant Ave., Columbus 16, Ohio
18. Continental-Diamond Fibre Co., Newark, Del.
19. Contour Extrusion Co., 517 Fayette Ave., Mamaroneck, N.Y.
20. Davis Plastics Co., Joseph, Schuyler & Quincy Ave., Arlington, N. J.
21. Deerfield Plastics Co., Inc., 271 Main St., S. Deerfield, Mass.
22. Dow Chemical Co., The, Midland, Mich.
23. du Pont de Nemours and Co., Inc., E.I., Film Dept., Wilmington, Del.
24. Durethene-Koppers Co., Inc., 7001 W. 60th St., Chicago 38, Ill.; 5600 W. Arbor Vitae St., Los Angeles, Calif.
25. Eastman Kodak Co., Rochester 4, N.Y.
26. Elm Coated Fabrics Co., 261 5th Ave., New York 16, N.Y.
27. Extruders, Inc., 3232 West El Segundo Blvd., Hawthorne, Calif.
28. Extrudo-Film Corp., 36-35 36th Street, Long Island City 6, N.Y.
29. Firestone Plastics Co., Pottstown, Pa.
30. Garlock Packing Co., Palmyra, N.Y.
31. General Plastics Corp., 1400 N. Washington St., Marion, Ind.
32. General Tire & Rubber Co., Pennsylvania Div., Jeannette, Pa.
33. Gering Products Inc., N. 7th St. & Monroe Ave., Kenilworth, N.J.
34. Goodrich Co., The B. F., Akron 18, Ohio
35. Goodyear Tire & Rubber Co., Akron 16, Ohio
36. Gordon-Lacey Chemical Products Co., Inc., Maspeth, L.I., N.Y.
37. H & R Industries, 344 E. Walnut St., Nazareth, Pa.
38. Harte & Co., Inc., 16 E. 34th St., New York 16, N.Y.
39. Imperial Chemical Industries Ltd., Millbank, London, S.W. 1, England
40. Kendall Co., 309 W. Jackson Blvd., Chicago 6, Ill.
41. Midwest Plastic Products Co., 1801 Chicago Road, Chicago Heights, Ill.
42. Minnesota Mining & Mfg. Co., 900 Fauquier Ave., St. Paul 6, Minn.
43. Mono-Sol Corp., 407 County Line Road, Gary, Ind.
44. Monsanto Chemical Co., Plastics Div., Springfield 2, Mass.
45. Natvar Corp., 211 Randolph Ave., Woodbridge, N.J.
46. Nixon Nitration Works, Nixon, N.J.
47. Olin Film Div., Ecusta Paper Corp., subsidiary of Olin Mathieson Chemical Corp., 655 Madison Ave., New York 21, N.Y.
48. Pantasote Co., 415 Madison Ave., New York 17, N.Y.
49. Plastex Process Co., 230 W. Passaic St., Maywood, N.J.
50. Plastic Film Corp., 475 Fifth Ave., New York 17, N.Y.
51. Plastic Horizons Inc., 2 E. 5th St., Paterson 1, N.J.
52. Plax Corp., P.O. Box 1019, Hartford, Conn.
53. Plicose Mfg. Corp., 16 E. 34th St., New York 16, N.Y.
54. Poly Plastic Products, Inc., 2 4th Ave., Paterson 4, N.J.
55. Polymer Corp. of Penna., 2140 Fairmont Ave., Reading, Pa.
56. Polypenco, Inc., 2150 Fairmont Ave., Reading, Pa.
57. Presto Plastics Products Co., Inc., 11 E. 26th St., New York 10, N.Y.
58. Rand Rubber Co., Summer Ave. & Halsey St., Brooklyn 16, N.Y.
59. Reliance Plastic and Chemical Corp., 110 Kearney St., Paterson 2, N.J.
60. Respro, Div. of The General Tire and Rubber Co., 530 Wellington Ave., Cranston 10, R.I.
61. Reynolds Metals Co., Plastics Div., P.O. Box 128, Grottoes, Va.
62. Ross & Roberts Co., Div. of Pollak Industrial Corp., 1299 W. Broad St., Stratford, Conn.
63. Rotuba Extruders, Inc., 437 88th St., Brooklyn 9, N.Y.
64. Rubber Corp. of America, New South Road, Hicksville, L.I., N.Y.
65. Scranton Plastic Laminating Corp., 3218 Pittston Ave., Scranton, Pa.
66. Seiberling Rubber Co., Plastics Div., Newcomerstown, Ohio
67. Southern Plastics Co., 408 Pendleton St., Columbia, S.C.
68. Textileather Div., The General Tire and Rubber Co., 607 Madison Ave., Toledo 3, Ohio
69. United States Gasket Co., P.O. Box 93, Camden 1, N.J.
70. United States Rubber Co., 1230 Avenue of the Americas, New York 20, N.Y.
71. Visking Corp., Plastic Div., Terre Haute, Ind.
72. Waljohn Plastics, 437 88th St., Brooklyn 9, N.Y.
73. Westlake Plastics Co., Lenni Mills, Pa.
74. Worbla Ltd., Papiermuhle-Berne, Switzerland

*The values reported in this chart are only for films up to 0.01 in. in thickness. The information was obtained from various sources. Special grades of these materials may be obtained which excel in some particular property. Manufacturers should be consulted for additional or specific information or for new uses of their materials.

[a]Square in. per lb. of film in 1 mil (0.001 in.) thickness. Figures may vary with resin plasticizer ratio. [b]ASTM D882, procedure B [c]ASTM D774 [d]Elmendorf test. Figures represent pull required to continue tear of 1 mil thick film after starting. Force required to start tear is too high to measure on same equipment and therefore is not normally determined. [e]SPI-ASTM D1004, static-weighing method. [f]Using 1 mil thick film and the Schopper Bending Endurance Tester, unless otherwise noted. [g]ASTM D570 [h]ASTM D697; values are in grams/24 hr./m.^{2}/mm. thickness/cm. Hg at 25°C. [i]Code for rating: E = Excellent, G = Good, M = Moderate, F = Fair, P = Poor. [j]Except aliphatic and petroleum hydrocarbons. [k]Except H_2SO_4 and HNO_3. [l]Except NH_4OH. [m]Except ketones and esters. [n]Except chlorinated solvents, ketones, esters, and hot aromatic hydrocarbons. [o]Except hydrocarbons and chlorinated solvents. [p]These compositions are the thermoplastic materials that gradually become softer as the temperature increases. The maximum and minimum service temperature will depend on formula of material, design of part and service conditions such as amount of stressing, humidity, etc. Requirements for resistance to heat and cold should be considered as special problems. Where a range of values is given in the chart, the low value is the limiting temperature for continuous exposure and the high value for intermittent exposure. [q]ASTM D1204. [r]Paragraph 4.10 in Commercial Standard CS192-53. [s]Grams/24 hr./100 sq. in. at 100°F. and 90% relative humidity. [t]cc./24 hr./100 sq. in. at 25°C. and 0% relative humidity. [u]cc./24 hr./100 sq. in./mil thickness/cm. Hg at 25°C.

LIST OF MANUFACTURERS AND SUPPLIERS OF RESINS AND ADHESIVES*

1. Acme Resin Corp., 1401 Circle Ave., Forest Park, Ill. (A)
2. Acryvin Corp. of America, 470 E. 99th St., Brooklyn 36, N.Y. (A)
3. Adhesive Engineering, San Carlos, Calif. (A)
4. Adhesive Products Corp., New York 60, N.Y. (RA)
5. Adhesive Products Inc., Albany 10, Calif. (A)
6. Aero Research, Ltd., Cambridge-Duxford, England (A)
7. Alkydol Laboratories, Inc., Cicero 50, Ill. (RA)
8. American Cyanamid Co., Plastics and Resins Div., 30 Rockefeller Plaza, New York 20, N.Y. (RA)
9. American Latex Products Corp., Hawthorne, Calif. (A)
10. American Lucoflex Inc., 500 5th Ave., New York 36, N.Y. (A)
11. American-Marietta Co., Adhesive, Resin and Chemical Div., 3400 13th Ave., S.W., Seattle 4, Wash. (RA)
12. American Products Manufacturing Co., New Orleans 18, La. (A)
13. Amoco Chemicals Corp., 910 S. Michigan Ave., Chicago 80, Ill. (R)
14. Angier Adhesives, Div. of Interchemical Corp., 120 Potter St., Cambridge 42, Mass. (A)
15. Arabol Mfg. Co., 110 E. 42nd St., New York 17, N.Y. (A)
16. Archer-Daniels-Midland Co., Minneapolis 2, Minn. (A)
17. Aries Laboratories, Inc., New York 17, N.Y. (A)
18. Armour and Co., 1355 W. 31st St., Chicago 9, Ill. (A)
19. Armstrong Cork Co., Lancaster, Pa. (A)
20. Armstrong Products Co., P.O. Box 1, Warsaw, Ind. (A)
21. Atlas Mineral Products Co., Mertztown, Pa. (A)
22. Atlas Powder Co., Wilmington 99, Del. (A)
23. Atlas Synthetics Corp., Long Island City 1, N.Y. (R)
24. B.B. Chemical Co., 784 Memorial Drive, Cambridge 39, Mass. (A)
25. Bakelite Co., Div. of Union Carbide and Carbon Corp., 30 E. 42nd St., New York 17, N.Y. (RA)
26. Barrett Div., Allied Chemical & Dye Corp., 40 Rector St., New York 6, N.Y. (RA)

29. Bloomingdale Rubber Co., Aberdeen, Md. (A)
30. Bond Adhesives Co., Box 406, Main P.O., Jersey City 3, N.J. (A)
31. Booty Resineers, Inc., 112 Jefferson St., Newark, Ohio (R)
32. Borden Co., The, Chemical Div., 350 Madison Ave., New York 17, N.Y. (RA)
33. British Resin Products Ltd., London S.W. 1, England (A)
34. Canadian Industries Ltd., Montreal, Canada (R)
35. Carbide and Carbon Chemicals Co., Div. of Union Carbide and Carbon Corp., 30 E. 42nd St., New York 17, N.Y. (RA)
36. Carboline Co., 331 Thornton Ave., St. Louis 19, Mo. (A)
37. Catalin Corp., 1 Park Ave., New York 16, N.Y. (RA)
38. Celanese Corp. of America, Plastics Div., 290 Ferry St., Newark 5, N.J. (RA)
39. Chemical Coatings and Engineering Co., Inc., Edgemont, Pa. (A)
40. Chemical Development Corp., Danvers, Mass. (A)
41. Chemical Process Co., 901 Spring St., Redwood City, Calif. (R)
42. Ciba Co., Inc., Plastics Div., Kimberton, Pa. (R)
43. Colton Chemical Co., 1747 Chester Ave., Cleveland 14, Ohio (R)
44. Compo Chemical Co., Inc., Boston 14, Mass. (A)
45. Cordo Chemical Co., 34 Smith St., Norwalk, Conn. (A)
46. Corn Products Sales Co., Chemical Div., New York 4, N.Y. (A)
47. Cycleweld Cement Products Div., Chrysler Corp., 5437 W. Jefferson, Trenton, Mich. (A)
48. Dennis Chemical Co., 2701 Papin St., St. Louis 3, Mo. (A)
49. Dewey and Almy Chemical Co., Div. of W.R. Grace and Co., Cambridge 40, Mass. (A)
50. Dow Chemical Co., The, Midland, Mich. (RA)
51. Dow Corning Corp., Midland, Mich. (RA)
52. E.I. duPont de Nemours and Co., Wilmington 98, Del. (RA)
53. Durez Plastics Div., Hooker Electrochemical Co., 888 Walck Road, North Tonawanda, N.Y. (RA)
54. Eastman Chemical Products, Inc., Kingsport, Tenn. (R)
55. Emerson and Cuming, Inc., Canton, Mass. (A)
56. Epoxylite Corp., El Monte, Calif. (A)
57. Farrington Texol Corp., Walpole, Mass. (A)
58. Federal Adhesives Corp., 210 Wythe Ave., Brooklyn 11, N.Y. (A)
59. Flintkote Co., Atlas Adhesives Div., Philadelphia 27, Pa. (A)
60. Formica Corp., 4614 Spring Grove Ave., Cincinnati 32, Ohio (A)
61. H.B. Fuller Co., 181 W. Kellogg Blvd., St. Paul 2, Minn. (A)
62. Furane Plastics Inc., Los Angeles 39, Calif. (RA)
63. General Aniline and Film Corp., New York 14, N.Y. (R)
64. General Electric Co., Pittsfield, Mass. (RA)
65. General Latex and Chemical Corp., Cambridge 39, Mass. (A)
66. General Mills, Inc., Chemical Div., P.O. Box 191, Kankakee, Ill. (RA)
67. B.F. Goodrich Co., 500 S. Main St., Akron 18, Ohio (RA)
68. Goodyear Tire and Rubber Co., Chemical Div., Akron 16, Ohio (A)
69. Gordon-Lacey Chemical Products Co., Maspeth, Long Island, N.Y. (A)
70. Griffin Chemical Co., Div. of Nopco Chemical Co., 1000 16th St., San Francisco 7, Calif. (R)
71. Harwick Standard Chemical Co., Akron 5, Ohio (A)
72. Hercules Powder Co., Wilmington 99, Del. (R)

*This list includes sources of bonding materials for compounding adhesives, indicated by (R), and sources of adhesive compositions prepared from the bonding materials, indicated by (A). The adhesives described on this chart are those formulated primarily with one type of plastic base. Many commercial adhesives are made up of complex mixtures of different resins in order to attain a combination of properties not found in a single type of base. The manufacturers of adhesives should be consulted before making a choice of material.

TRADE DESIGNATIONS	MANUFACTURERS OR SUPPLIERS OF RESINS OR ADHESIVES (*See list below for key to numbers*)
30g. Arcco (32), Bakelite (25), Bondmaster (123), Butvar (127), Dennis (48), Farrington (57), Laco (81), Midland (88), Placco (32), Plastibond (69), Plasticweld (83), Plastilock (67), Polybond (114), Reslac (32), Resyn (95), VC (126)	4, 24, 25, 30, 32, 48, 52, 57, 67, 69, 76, 81, 83, 88, 95, 107, 112, 114, 116, 122, 123, 126, 127, 145
30h. Ampcoflex (21), Anodex (67), Arcco (32), Bakelite (25), Bondmaster (123), Bostik (24), BRC (29), CD Cement (40), Compo (44), Cordo-Bond (45), Dennis (48), Fedco (58), Laco (81), Loven (84), Midland (88), Pee Vee Cee (21), Placco (32), Plastibond (69), Plastigrip (4), Plastilock (67), Plastite (110), Polybond (114), Polyco (32), Reslac (32), Resyn (95), Rubbagrip (122), Upaco (136), Vinylgrip (4), Watson-Standard (143)	4, 14, 19, 21, 24, 25, 29, 32, 40, 44, 48, 52, 58, 67, 69, 81, 84, 88, 95, 103, 107, 110, 112, 114, 116, 122, 123, 126, 136, 143, 145
30i. API (5), Arcco (32), Bakelite (25), Bond (30), Bondmaster (123), Bostik (24), CD Cement (40), Compo (44), Cordobond (45), Dennis (48), Fedco (58), Fuller (61), Helix (28), Hewbind (74), Kotol (97), Midland (88), Placco (32), Plastibond (69), Plastilock (67), Plastite (110), Pliastic (103), Polybond (114), Polyco (32), Reslac (32), Resyn (95), Rubbagrip (122), Stabond (9), Synco (132), Tygobond (139), Upaco (136), U-Sement (138), Vinylgrip (4), Watson-Standard (143), Zerok (21), 3 M (89)	4, 5, 9, 14, 15, 19, 21, 24, 25, 28, 30, 32, 40, 44, 48, 52, 58, 61, 67, 69, 74, 76, 78, 88, 89, 95, 97, 103, 107, 110, 112, 114, 116, 122, 123, 126, 132, 136, 138, 139, 143, 144, 145
30j. PVP (63)	63
30k. Arcco (32), Bondmaster (123), CD Cement (40), Cordo-Bond (45), Dennis (48), B.F. Goodrich (67), Midland (88), Miracle (90), Ohio (102), Placco (32), Polybond (114), Polyco (32), Reslac (32), Resyn (95), Rubbagrip (122), Saran (50), Upaco (136), Vinylgrip (4), Watson-Standard (143), 3 M (89)	4, 14, 19, 32, 40, 48, 50, 58, 67, 76, 88, 89, 90, 95, 102, 107, 112, 114, 116, 122, 123, 126, 136, 143, 145
31. API (5), Fuller (61), Indu-Sealz (97), Midland (88), Polybond (114), Resimelt (103), Reswax (32), Resyn (95), Upaco (136)	5, 14, 15, 32, 61, 88, 92, 95, 97, 103, 114, 116, 136, 145
32. Arcco (32), Argo (46), Midland (88), Paisley (103), Placco (32), Polybond (114), Reslac (32), Upaco (136)	32, 46, 88, 103, 114, 136, 145

[b] Code for solvents: A = Alcohols; Cl = Chlorinated hydrocarbons; E = Fatty acid esters; H = Aromatic hydrocarbons; HA = Aliphatic hydrocarbons; K = Ketones; W = Water (solution or emulsion).

[c] Code for rating: E = Excellent; G = Good; M = Moderate; F = Fair; P = Poor.

LIST OF MANUFACTURERS AND SUPPLIERS OF RESINS AND ADHESIVES* (*Continued*)

73. Heresite & Chemical Co., Manitowoc, Wis. (RA)
74. C.B. Hewitt and Bros., Inc., New York 13, N.Y. (A)
75. Houghton Laboratories, Inc., 322 Bush St., Olean, N.Y. (A)
76. Hughes Glue Co., Detroit 7, Mich. (A)
77. Imperial Chemical Industries Ltd., London S.W. 1, England (R)
78. Interchemical Corp., Finishes Div., 67 W. 44th St., New York 36, N.Y. (A)
79. Irvington Chemical Div., Minnesota Mining and Manufacturing Co., 500 Doremus Ave., Newark 5, N.J. (A)
80. Koppers Co., Inc., Chemical Div., Pittsburgh 19, Pa. (RA)
81. Lawrence Adhesive and Chemical Co., Lawrence, Mass. (A)
82. Lebec Chemical Corp., Paramount, Calif. (A)
83. Lithgow Chemical Co., Div. of Reichhold Engineering and Plastics Co., 12827 E. Imperial Highway, Norwalk, Calif.
84. Loven Chemical of California, Newhall, Calif. (RA)
85. Magic Chemical Co., Brockton 2, Mass. (A)
86. Marblette Corp., Long Island City 1, N.Y. (RA)
87. Marbon Chemical Div., Borg-Warner Corp., Gary, Ind. (A)
88. Midland Adhesive and Chemical Corp., Detroit 20, Mich. (A)
89. Minnesota Mining and Mfg. Co., Adhesives and Coatings Div., 411 Piquette Ave., Detroit 2, Mich. (A)
90. Miracle Adhesives Corp., 214 E. 53rd St., New York 22, N.Y. (A)
91. Mobay Chemical Co., St. Louis 4, Mo. (A)
92. Monsanto Chemical Co., Plastics Div., Springfield 2, Mass.; Western Div., 911 Western Ave., Seattle 4, Wash. (RA)
93. Multiplastics Div., Curd Enterprises, Inc., 3337 Lincoln St., Franklin Park, Ill. (R)
94. Narmco Resins and Coatings Co., Costa Mesa, Calif. (A)
95. National Adhesives Div., National Starch Products Co., 270 Madison Ave., New York 16, N.Y. (RA)
96. National Casein Co., 601 W. 80th St., Chicago 20, Ill. (RA)
97. Naugatuck Chemical Div., U.S. Rubber Co., Naugatuck, Conn. (RA)
98. Neville Chemical Co., Neville Island, Pittsburgh 25, Pa. (R)
99. New York Quinine and Chemical Works, Inc., The, 50 Church St., New York 8, N.Y. (R)
100. Nova Chemical Corp., 147 Waverly Place, New York 14, N.Y. (R)
101. Nureco Inc., Cranston 10, R.I. (RA)
102. Ohio Adhesives Corp., New Philadelphia, Ohio (A)
103. Paisley Products Inc., Div. of Morningstar Nicol Inc., 630 W. 51st St., New York 19, N.Y. (A)
104. Pennsylvania Industrial Chemical Corp., Clairton, Pa. (R)
105. Perkins Glue Co., Lansdale, Pa. (RA)
106. Philadelphia Quartz Co., Philadelphia 6, Pa. (RA)
107. Pierce and Stevens, Inc., 710 Ohio St., Buffalo 3, N.Y. (A)
108. Pittsburgh Plate Glass Co., Paint Div., Pittsburgh, Pa. (R)
109. Plastics Engineering Co., Sheboygan, Wis. (R)
110. Plastite Adhesives Corp., Chicago 10, Ill. (RA)
111. Poly Resins, Sun Valley, Calif. (R)
112. Polymer Chemical Co., Cincinnati 12, Ohio (A)
113. Polymer Corp. of Pa., 2140 Fairmont Ave., Reading, Pa. (A)
114. Polymer Industries Inc., Springdale, Conn. (A)
115. Polypenco, Inc., Reading, Pa. (A)
116. Pyroxylin Products, Inc., Chicago 32, Ill.; Paoli, Pa. (A)
117. Raffi and Swanson, Inc., Wilmington, Mass. (A)
118. Reichhold Chemicals, Inc., White Plains, N.Y. (RA)
119. Ren Plastics Inc., Lansing 4, Mich. (A)
120. Reynolds Chemical Products Co., Ann Arbor, Mich. (A)
121. Rohm & Haas Co., Resinous Products Div., 222 W. Washington Sq., Philadelphia 5, Pa. (RA)
122. Rubba, Inc., 1015 E. 173rd St., New York 60, N.Y. (A)
123. Rubber and Asbestos Corp., Bloomfield, N.J. (A)
124. Rubber Corp. of America, Latex and Chemical Div., New South Road, Hicksville, Long Island, N.Y. (A)
125. Schenectady Varnish Co., Inc., Schenectady 1, N.Y. (R)
126. Schwartz Chemical Co., Inc., New York 23, N.Y. (A)
127. Shawinigan Products Corp., New York 1, N.Y. (RA)
128. Shell Chemical Corp., New York 17, N.Y. (RA)
129. Slomons Laboratories, Inc., Long Island City 1, N.Y. (A)
130. Stein-Hall and Co., Inc., New York 17, N.Y. (A)
131. Swift and Co., 4115 Packers Ave., Chicago 9, Ill. (A)
132. Synco Resins, Inc., Bethel, Conn. (RA)
133. Synvar Corp., 415 E. Front St., Wilmington 99, Del. (RA)
134. Tennessee Eastman Co., Kingsport, Tenn. (R)
135. UBS Chemical Corp., Cambridge 42, Mass. (A)
136. Union Paste Co., 1605 Hyde Park Ave., Hyde Park 36, Mass. (A)
137. U.S. Plywood Corp., 55 W. 44th St., New York 18, N.Y. (RA)
138. U.S. Rubber Co., Rockefeller Center, New York 20, N.Y. (RA)
139. U.S. Stoneware Co., 100 Brimfield Rd., Akron 9, Ohio (A)
140. Valite Corp., 726 Whitney Bldg., New Orleans 12, La. (RA)
141. Varcum Chemical Corp., Packard Rd., Niagara Falls, N.Y. (RA)
142. Velsicol Chemical Corp., Chicago 11, Ill. (R)
143. Watson-Standard Co., 225 Galveston Ave., Pittsburgh 30, Pa. (R)
144. Williamson Adhesives, Inc., 8220 Kimball Ave., Skokie, Ill. (A)
145. Wilross Products Co., 20 Fourth Ave., Hawthorne, N.J. (A)
146. Xylos Rubber Co., Div. of The Firestone Tire and Rubber Co., Akron 1, Ohio (A)
147. Wm. Zinsser and Co., Inc., New York 19, N.Y. (A)

The manufacturers of adhesives should be consulted before making a choice of material.

Coatings Chart

TYPE OF PLASTIC BASE	TRADE DESIGNATIONS OF RESINS OR COATINGS	MANUFACTURERS OR SUPPLIERS OF RESINS OR COATINGS (See list on pp. 578-9 for key to numbers)
1. Acrylate and methacrylate resins	Acrylac (170), Acryloid (156), Acrylon (27), Arcco (27), AT (160), Bedacryl (93), Cordobond (46), Corrocote (38), Coverlac (169), Dennis (50), Farrington (66), Gordon-Lacey (84), Hycryl (178), Inceloid (12), Kotol (124), Krylon (103), Logo (107), Lucite (57), MCW (114), Midland (113), Nopco (128), Nubeloid (80), Placco (27, 49), Placquer (49), Polyco (27), Polyflex (95), Polyplex (172), Reslac (27), Resyn (123), Rez-N-Lac (160), Rhoplex (156), Stanley (171), Ubatol (178), Wilross (187), 3 M (115)	4, 12, 17, 18, 27, 31, 38, 40, 46, 49, 50, 57, 66, 80, 84, 93, 95, 96, 98, 103, 107, 113, 114, 115, 123, 124, 128, 139, 143, 147, 148, 150, 156, 157, 160, 169, 170, 171, 172, 173, 176, 178, 183, 187
2. Alkyd resins (phthalic anhydride-polyhydric alcohol-oil combinations)	Alkydol (3), Amberlac (156), Armorcord (16), Aulflex (95), Bar-ox (177), Beckosol (151), Carbosol (132), Cellolyn (89), Crown (48), Duraplex (156), Durez (58), Dyal (166), Epok (30), Falkyd (34), FCD (71), Glyptal (77), Kotol (124), Logo (107), MCW (114), Mirasol (132), Oxalkyd (186), Paralac (93), Paraplex (156), Plaskon (22), Rez-N-Lac (160), Rezyl (8), Schenectady (159), Stanley (171), Sulivar (172), Syntex (99), Varkyd (111), Walkyd (151), Wilross (187)	3, 8, 16, 17, 18, 22, 28, 30, 31, 34, 44, 48, 58, 61, 71, 77, 80, 89, 93, 95, 98, 99, 107, 111, 114, 124, 132, 139, 148, 151, 156, 159, 160, 166, 170, 171, 172, 176, 177, 183, 187, 189
3. Allyl starch resin	Amercoat (4)	4, 80, 139
4. Asphalts	Arcco (27), Atlastic (19), Lebec (105), Loven (108), Midland (113), Nebony (125), Pioneer (188), Placco (27), Resinex (88), Reslac (27), Transphalt (136), Witcote (188), 3 M (115)	12, 19, 27, 80, 88, 105, 108, 113, 115, 116, 136, 188
5. Cellulose acetate	Acetoplex (172), Arcco (27), CD (39), Cymel (8), Dyal (166), Farrington (66), Gordon-Lacey (84), Hercules (89), Inceloid (12), Logo (107), MCW (114), Midland (113), Placco (27), Reslac (27), Rez-N-Lac (160), Wilross (187)	7, 12, 17, 27, 37, 39, 40, 57, 59, 66, 80, 84, 89, 98, 107, 113, 114, 115, 118, 139, 143, 147, 148, 150, 160, 166, 170, 172, 174, 187
6. Cellulose acetate butyrate	Arcco (27), Butaflex (172), Gordon-Lacey (84), Half-Second Butyrate (59), Lebec (105), Logo (107), MCW (114), Midland (113), Placco (27), Plastrip (145), Reslac (27), Resyn (123), Rez-N-Lac (160), Seal-Peel (161), Stanley (171), Thermo-Cote (25), Tool-Dip (142), Westcoat (184), Wilross (187)	17, 18, 25, 27, 40, 59, 65, 80, 84, 95, 98, 105, 107, 113, 114, 123, 139, 142, 143, 145, 147, 148, 150, 160, 161, 170, 171, 172, 174, 184, 187
7. Cellulose, carboxymethyl	Carbose (190), Cellofas (93), Hercules CMC (89), Logo (107), Midland (113), Sodium CMC (57)	31, 57, 89, 93, 107, 113, 139, 143, 160, 190
8. Cellulose, ethyl	Ethocel (54), Farrington (66), Gordon-Lacey (84), Hercules (89), Inceloid (12), Logo (107), MCW (114), Midland (113), Resyn (123), Rez-N-Lac (160), Thermo-Cote (25), Tool-Dip (142), Westcoat (184), Wilross (187)	12, 17, 18, 25, 40, 54, 66, 80, 84, 89, 95, 107, 113, 114, 123, 139, 142, 143, 147, 148, 160, 184, 187
9. Cellulose, hydroxyethyl	Cellosize (32), Logo (107), Midland (113), Whirlsint (122, 144)	32, 40, 107, 113, 139, 143
10. Cellulose, ethyl hydroxyethyl	EHEC (89), Midland (113)	89, 113, 160
11. Cellulose, methyl	Methocel (54)	54
12. Cellulose nitrate	Arcco (27), Armolac (16), Aultone (95), Blue Knight (95), CD (39), Dennis (50), Farrington (66), Hercules (89), Inceloid (12), Logo (107), MCW (114), Midland (113), Nik-o-lac (127), Placco (27), Reslac (27), Resyn (123), Rexlance (154), Rez-N-Lac (160), Stanley (171), Wilross (187)	8, 12, 16, 17, 18, 27, 28, 39, 40, 50, 57, 60, 80, 89, 95, 98, 107, 113, 114, 118, 123, 127, 139, 143, 147, 148, 150, 154, 160, 170, 171, 174, 176, 187
13. Cellulose propionate	Logo (107)	36, 107, 160
14. Chlorinated paraffins	Cereclor (93), Chlorowax (53), Clorafin (89), Halowax (21), Logo (107), Midland (113), Stan-Chlor Oil (88), Wilross (187)	21, 31, 53, 80, 88, 89, 91, 93, 107, 113, 139, 143
15. Chlorinated rubber	Alloprene (93), Apco (2), Arcco (27), Armorcote (16), Carboline (33), Corrocote (38), Dennis (50), Farrington (66), Gordon-Lacey (84), Laco (104), Lebec (105), Logo (107), MCW (114), Midland (113), Para-Stonetex (177), Paratex (177), Parlon (89), Placco (27), Resimene (118), Reslac (27), Rexadur (154), Rez-N-Lac (160), Roxaprene (95), Stanley (171), Texkote (142), Vulcabond (10), Wilross (187), Zerok (19), 3 M (115)	2, 9, 10, 16, 19, 27, 31, 33, 38, 50, 66, 80, 84, 89, 93, 95, 104, 105, 107, 113, 114, 115, 118, 139, 142, 143, 147, 154, 160, 170, 171, 176, 177, 178, 187
16. Coumarone resins	Cumar (22), Durez (58), Epok (30), Inceloid (12), Neville R (125), Nevindene (125), Nuba (125), Paradene (125), Piccoumaron (136), Piccovar (136), Wilross (187)	12, 22, 30, 58, 80, 85, 88, 125, 136, 139, 143, 147, 181, 187
17. Cyclized rubber	Acidseal (82), Alpex (3), Pliolite NR (83)	80, 82, 83, 139, 143, 147
18. Epoxy resins (epichlorohydrin bisphenol resins)	Alfane (19), Alk-o-flex (3), Amercoat (4), Amphesive (19), Araldite (41), Aritemp (15), Armorcoid (16), Bakelite (21), Beckosol (151), Carboline (33), Cardolite (97), CD (39), Chem-Fast (177), Devran (51), Duro-Lok (123), Dyphenite (166), Epi-Kote (74), Epiphen (27), Epi-Rez (99), Epi-Tex (99), Epi-Var (99), Epocast (60, 74), Epok (30), Epolac (104), Epon (165), Eponite (172), Epoxine (95), Epoxylite (64), Flawmaster (24), Helix (24), Hi-Bake Sterilkote (28), Hysol (92), Lithgow (106), Logo (107), Loven (108), Maraset (109), MCW (114), Midland (113), Mirasol (132), Napon (19), Nepoxide (19), Nipoxin (95), Nu-Pon (80), Nureco (130), Perma-Skin (50), Poly-Kast (142), Polyox (151), Ren (152), Resiweld (72), Rez-N-Lac (160), Schenectady (159), Sock-O-Plastic, (168), Speedrex (177), Stanley (171), Wilross (187), 3 M (115)	4, 14, 15, 16, 18, 19, 21, 24, 27, 28, 30, 33, 38, 39, 40, 41, 44, 50, 51, 60, 61, 64, 72, 74, 80, 92, 95, 97, 98, 99, 104, 106, 107, 108, 109, 113, 114, 115, 122, 123, 130, 132, 139, 142, 144, 147, 148, 150, 151, 152, 156, 159, 160, 165, 166, 168, 170, 171, 172, 176, 177, 183, 187
19. "Ester-type" resins-oil reactive (bicyclo-heptane dicarboxylic acid, and related esters with drying oils)	Stanley (171)	80, 139, 160, 171, 183
20. Ethylene resins (polyethylene)	A-C (162), Agilene (5), Alathon (57), Bakelite (21), Dow (54), Dylan (102), Epolene (59), Fedco (67), Fortiflex (36), Hi-fax (89), Ladcote (56), Logo (107), Marlex (138), Modulene (119), Resinite (153), Super Modulene (119), Whirlsint (122, 144)	5, 21, 37, 54, 56, 57, 59, 67, 80, 82, 87, 102, 107, 119, 122, 138, 139, 144, 147, 153, 162

[b]Code for drying classification: A = Air drying; B = Baking; F = Force drying 120–150 °F.
[c]Code for rating: E = Excellent; G = Good; M = Moderate; F = Fair; P = Poor

TYPE OF PLASTIC BASE	TRADE DESIGNATIONS OF RESINS OR COATINGS	MANUFACTURERS OR SUPPLIERS OF RESINS OR COATINGS *(See list on pp. 578-9 for key to numbers)*
21. Fluoroethylene resins	Agifluor (5), Bakelite (21), Corrocote (38), Exon (68), Fluron (179), Kel-F (100), Pee Vee Seal (19), Polyfluoron (1), Teflon (57)	1, 5, 21, 38, 57, 68, 80, 100, 179
22. Furan resins	Alkaloy (19), Aikor (19), Carboline (33), Duralon (179), Durez (58), Dyphene (166), Furatone (97), Furnane (19), Griffin (86), Jet-Kote (74), Lithgow (106), Loven (108), Resin X (74), Resistojet (74), Super-Beckacite (151), Tybon (26)	19, 26, 33, 58, 74, 80, 86, 97, 106, 108, 151, 166, 179
23. Hydrocarbon resins (derived from petroleum)	Arcco (27), Amercoat (4), Atlastic (19), JC (19), Loven (108), Midland (113), Nebony (125), Neville (125), Panarez (13), Piccopale (136), Piacco (27), Reslac (27), Velsicol (181), Wilross (187), 3 M (115)	4, 13, 19, 27, 28, 80, 88, 108, 113, 115, 125, 136, 139, 143, 181, 187
24. Isobutylene resins (polyisobutylene)	Logo (107), Oppanol B (129), Vistanex (63), Wilross (187)	56, 63, 80, 107, 129, 139, 143, 181, 187
25. Ketone resins	Bakelite (21), Corrocote (38)	21, 38, 40, 80, 139
26. Maleic resins	Amberol (156), Arcco (27), Beckacite (151), Carbasol (132), Cellolyn (89), Crown (48), Durez (58), Dyal (166), Dymal (166), Epok (30), FCD (71), Falkote (34), Lewisol (89), Mirasol (132), Pentalyn (89), Petrex (89), Piacco (27), Plaskon (22), Reslac (27), Rexatherm (154), Schenectady (159), Stanley (171), Synaryl (3), Syntex (99), Synvar V (173), Teglac (8), Wilross (187)	3, 8, 22, 30, 34, 40, 44, 48, 57, 58, 71, 76, 80, 89, 94, 95, 99, 132, 139, 147, 150, 151, 154, 156, 159, 166, 171, 172, 173, 183, 187
27. Melamine resins	Dymal (166), Epok (30), Logo (107), Plaskon (22), Polymerin (95), Resimene (118), Stanley (171), Super-Beckamine (151), Synvarol (173), Uformite (156), Wilross (187)	8, 22, 30, 40, 61, 80, 95, 107, 118, 139, 147, 151, 156, 159, 166, 171, 173, 183, 187
28. Natural resins (batu, congo, copal, damar, elemi, kauri, manila, Sandarac, etc.)	Innes (38), Kopol (151), Schenectady (159), Stanley (171), Wilross (187)	71, 80, 94, 147, 151, 159, 171, 183, 187
29. Oleo-resinous materials (combinations of oils, and natural and synthetic resins)	Alkydol (3), Amberlac (156), Armitage (16), Bakelite (21), Beckosol (151), Cellolyn (89), Crown (48), Duraplex (156), Durez (58), Dyal (166), Falkyd (34), GE (77), Ledwax (56), Lithgow (106), Miravar (132), Plaskon (22), Resimene (118), Rezyl (8), Schenectady (159), Stanley (171), Sullvar (172), Syntex (99), Synvaren (173), Wilross (187)	3, 8, 16, 21, 22, 27, 28, 34, 44, 48, 56, 58, 71, 77, 80, 89, 94, 95, 96, 99, 101, 106, 118, 126, 132, 139, 140, 150, 151, 156, 159, 166, 170, 171, 172, 173, 176, 183, 187
30. Phenol-formaldehyde modified and drying oil combinations (including paraphenylphenol-formaldehyde resins and alkylated phenol resins)	Acikote (179), Alkydol (3), Amberol (156), Armitage (16), Bakelite (21), Beckacite (151), Beckopol (151), Bedesol (93), Cardolite (97), Crown (48), Durez (58), Dyphenite (166), Epok (30), FCD (71), GE (77), Heresite (90), Hydrophen (151), Korez (19), Lamophene (142), Lebec (105), Logo (107), Loven (108), Methylon (77), McCloskey (111), Nevillac (125), Nobeilac (151), Pentalyn (89), Plaskon (22), Plastilock (82), Schenectady (159), Stanley (171), Sullvar (172), Synaryl (3), Syntex (99), Synvarite (173), Varcum (180), Wilross (187)	3, 16, 19, 21, 22, 28, 30, 31, 44, 48, 58, 71, 77, 80, 82, 89, 90, 93, 95, 97, 98, 99, 105, 107, 108, 111, 121, 125, 139, 142, 151, 156, 159, 160, 166, 171, 172, 173, 176, 179, 180, 183, 187, 189
31. Phenol-formaldehyde pure resins (spirit-soluble, "heat-reactive" types)	Amberol (156), Amercoat (4), Bakelite (21), Bedesol (93), Carbasol (132), Carboline (33), Cosmalite (42), Durez (58), Durite (27), Dyphene (166), Epok (30), FCD (71), GE (77), Heresite (90), Kaston (142), Kotol (124), Lebec (105), Lithgow (106), Logo (107), Loven (108), Marblette (109), Methylon (77), Mirasol (132), Nobellon (151), Plaskon (22), Plenco (141), Plyophen (151), P.Q.L. (124), Resinox (118), Schenectady (159), Sock-O-Plastic (168), Stanley (171), Super-Beckacite (151), Synvarite (173), Varcum (180), Wilross (187)	1, 4, 21, 22, 27, 28, 30, 31, 33, 40, 42, 44, 58, 71, 77, 80, 90, 93, 95, 98, 105, 106, 107, 108, 109, 118, 124, 132, 139, 141, 142, 151, 156, 159, 160, 166, 168, 171, 173, 176, 180, 183, 187
32. Polyamide resins	Agilon (5), Arcco (27), BCI (23), Corrocote (38), Gordon-Lacey (84), Lithgow (106), Logo (107), Piacco (27), Reslac (27), Versamid (78), Whirlsint (122,144), Wilross (187)	5, 23, 27, 28, 38, 40, 57, 78, 80, 84, 87, 107, 122, 139, 144, 147, 183, 187
33. Polyamide-epoxy resins	Amercoat (43), Corrocote (38), Dennis (50), Duro-Lok (123), Epolac (104), Logo (107), MCW (114), Nureco (130), Stanley (171), Vulcabond (10), Wilross (187), 3 M (115)	4, 10, 14, 27, 28, 38, 50, 78, 104, 107, 114, 115, 130, 150, 160, 171, 187
34. Polyester resins	Alkydol (3), Ampreg (19), Atlac (20), Carboline (33), Cellobond (30), FCD (71), Daltolac (31), GE (77), Glidpol (80), Goodrich, B.F. (82), Hetron (91), IC (95), Isolite (159), Laminal (8), Logo (107), Loven (108), Marco (36), MCW (114), Nureco (130), Paraplex (156), Plaskon (22), Plastaloy (19), Polylite (151), Schenectady (159), Selectron (140), Vibrin (124)	6, 8, 20, 22, 27, 30, 31, 33, 36, 38, 46, 71, 77, 80, 82, 91, 93, 95, 107, 108, 114, 124, 130, 139, 151, 156, 159, 176, 183
— Polyethylene (see 20)		
35. Polyethylene glycols	Carbowax (32)	32
35a. Polysulfide-epoxy	Epoxylite (64), Nureco (130), Rez-Cote (19)	19, 35, 45, 46, 64, 73, 75, 114, 175
36. Rubbers, synthetic a. Polychloroprenes b. Butadiene-styrene c. Butadiene-styrene trile d. Isoprene-isobutylene e. Isoprene-styrene f. Polysulfide g. Polyacrylic h. Polybutadiene — Polyisobutylene (see 24)	Acrylon (27), Ameran (82), Apco (2), Arcco (27), Baytex (178), Butaprene (69), Butarez (138), Carboline (33), Chemigum (83), Compo (43), Corrocote (38), Dennis (50), Elprene (19), Geo-Flo (79), Goodrich, B.F. TYPE OF PLASTIC BASE	TRADE DESIGNATIONS OF RESINS OR COATINGS	MANUFACTURERS OR SUPPLIERS OF RESINS OR COATINGS (See list on pp. 578-9 for key to numbers)
39. Silicone-alkyd resins	Dow Corning (55), Dyal (166), FCD (71), Nubelon (80), Plaskon (22), Schenectady (159), Stanley (171), Syntex (99), Union Carbide (167), Vulcabond (10), Wilross (187)	10, 18, 22, 55, 71, 80, 99, 139, 159, 166, 167, 171, 183, 187
40. Silicone-phenolic	Dow Corning (55)	55, 80
41. Silicone rubber	GE (77), Silastic (55), Union Carbide (167)	55, 77, 167
42. Styrene resins (polystyrene)	Arcco (27), Bakelite (21), Calvoseal (106), CD (39), Dow Latex (54), Epok (30), Inceloid (12), KTPL (102), Ladcote (56), Loxite (69), Lustrex (118), Marbon (110), Midland (113), Nopco (128), Piccolastic (88,136), Placco (27), Plastiplex (172), Polyco (27), Polystyrolac (170), PS-Resin (54), Resgrip (2), Reslac (27), Rez-N-Lac (160), Stanley (171), Styroloid (170), Styrophane (170), Ubatol (178), Wallpol (151), Wilross (187)	2, 12, 17, 18, 21, 27, 30, 39, 54, 56, 69, 80, 83, 88, 102, 106, 107, 110, 113, 118, 128, 136, 139, 143, 147, 150, 151, 159, 160, 170, 171, 172, 176, 178, 187
43. Styrene-butadiene resins	Arcco (27), Butaprene (68), Carboline (33), Darex (52), Dow Latex (54), Gordon-Lacey (84), Kralastic (124), Laco (104), Lotol (124), Marbon (110), Midland (113), Placco (27), Pliolite (83), Plio-Tuf (83), Polyco (27), Polyplex (172), Reslac (27), Rez-N-Lac (160), Wilross (187), Zerok (19)	19, 27, 28, 33, 52, 54, 68, 80, 83, 84, 102, 104, 110, 113, 124, 139, 148, 160, 172, 176, 183, 187
44. Styrenated alkyd	Alkydol (3), Armorcord (16), Cycopol (8), Dennis (50), Dyal (166), FCD (71), Fosterite (185), MCW (114), Plaskon (22), Resimene (118), Schenectady (159), Stanley (171), Styresol (151), Styretex (99), Wilross (187)	3, 8, 16, 18, 22, 28, 40, 44, 50, 55, 71, 80, 95, 98, 99, 114, 139, 147, 148, 151, 159, 166, 170, 171, 172, 176, 183, 185, 187
45. Styrenated drying oils	Wilross (187)	3, 44, 80, 139, 187
46. Terpene resins	Indu-sealz (124), Marbon (110), Piccolyte (136), Schenectady (159), Wilross (187)	80, 88, 110, 124, 136, 139, 147, 159, 187
47. Terpene-phenolics	Crown (48), Durez (58), Schenectady (159), Super-Beckacite (151), Varcum (180), Wilross (187)	48, 58, 80, 151, 159, 180, 183, 187
48. Urea-formaldehyde resins and oil-resin combinations	Amerite (27), Arcco (27), Armorcoid (16), Beckamine (151), Beetle (8), Epok (30), Ful-O-Mite (72), Lebec (105), Loven (108), Midland (113), Paralac (93), Placco (27), Plaskon (22), Polymerin (95), Resimene (118), Reslac (27), Stanley (171), Syn-U-Tex (99), Synvarol (173), Uformite (156), Wilross (187)	8, 16, 22, 27, 28, 30, 31, 40, 72, 80, 93, 95, 98, 99, 105, 106, 108, 113, 118, 139, 147, 151, 156, 160, 170, 171, 173, 176, 187
49. Urethanes (polyurethanes)	Daltolac (93), Goodrich, B.F. (82), Isomelt (159), Mondur/Multron (117), Pelron (135), Suprasec (93)	31, 38, 82, 93, 117, 135, 148, 159
50. Vinyl acetate resins	Acetex (124), Ameran (82), Arcco (27), Bakelite (21), CD (39), Celanese (36), Corrocote (38), Crown (48), Darex (52), Dennis (50), Elvacet (57), Elvalon (57), Epok (30), Fuller (72), Gelva (164), Goodrich, B.F. (82), Gordon-Lacey (84), Griffco (86), Inceloid (12), Lemac (27), Midland (113), Nopco (128), Placco (27), Polyco (27), Poly-Tex (99), Reslac (27), Resyn (123), Stanley (171), Synvar VE (173), Vinac (42), Vinaplas-Lac (160), Vinymul (133), Wallpol (151), Wilross (187)	12, 14, 18, 21, 27, 28, 30, 36, 38, 39, 42, 46, 48, 50, 52, 57, 72, 80, 82, 84, 86, 98, 99, 106, 113, 123, 124, 128, 133, 139, 142, 143, 147, 148, 151, 160, 164, 170, 171, 173, 176, 187
51. Vinyl alcohol	Elvanol (57), Gelvatol (164), Lemol (27), Midland (113), Resyn (123), Vinol (42), 3 M (115)	27, 42, 46, 57, 113, 115, 123, 139, 143, 160, 164
52. Vinyl butyral resins	Amercoat (4), Arcco (27), Armorcote (16), Bakelite (21), Butacite (57), Butvar (164), Calvinac (106), Corogard (115), Dispersite (124), Goodrich, B.F. (82), Gordon-Lacey (84), MCW (114), Perma-Skin (50), Placco (27), Protectophene (142), Rand (149), Reslac (27), Spraylat (169), Stanley (171), Vy King (51), Wilross (187)	4, 16, 18, 21, 27, 28, 40, 50, 51, 57, 80, 82, 84, 106, 114, 115, 124, 139, 142, 143, 147, 149, 150, 160, 164, 169, 171, 176, 183, 187
53. Vinyl chloride resins	Ace-Flex (9), Ameran (82), Amercoat (4), Ampcoflex (19), Arcco (27), Armosol (16), Avaloid (98), Bakelite (21), Breon (29), Calvinac (106), CD (39), Chem-o-sol (40), Cordobond (46), Corrocote (38), Cyclon (120), Diamond PVC (53), Dow Latex (54), Elastosol (60), Epocast (60), Farrington (66), Firestone latex (68), Geon (81), Goodrich, B.F. (82), Gordon-Lacey (84), Inceloid (12), Kotol (124), Marvinol (124), Miccrosol (112), Midland (113), Opalon (118), Osco (131), Parcloid (134), Pee Vee Cee (19), Peel-Kote (120), Perma-Skin (50), Placco (27), Plastrip (145), Pliovic (83), Polyco (27), Polyprene (95), P-T-I (145), Rand (149), Resinite (153), Reslac (27), Resyn (123), Reynosol (155), Stanley (171), Sterilkote (28), Tool-Dip (142), Tygon (179), Vichrome (95), Vinaplas-Lac (160), Vinrex (154), Vygen (79), Vy King (99), Westoflex (184), Wilflex (70), Wilross (187)	9, 11, 12, 14, 16, 18, 21, 27, 28, 29, 38, 39, 40, 46, 50, 53, 54, 60, 61, 62, 65, 66, 68, 70, 79, 80, 81, 82, 83, 84, 95, 98, 99, 106, 112, 113, 118, 120, 123, 124, 131, 134, 139, 142, 143, 145, 147, 148, 149, 153, 154, 155, 157, 158, 160, 163, 170, 171, 176, 179, 183, 184, 187
54. Vinyl chloride-acetate resins (higher chloride types)	Airstrip (142), Ameran (82), Amercoat (4), Arcco (27), Armorhide (16), Bakelite (21), Breon (29), Carboline (33), CD (39), Cordobond (46), Corogard (115), Corrocote (38), Coverlac (169), Elastomer (60), Epocast (60), Exon (68), Gordon-Lacey (84), Inceloid (12), MCW (114), Midland (113), Nubelyn (80), Perma-Skin (50), Placco (27), Plastrip (145), Polyco (27), Rand (149), Reslac (27), Resyn (123), Reynosol (155), Sock-O-Plastic (168), Stanley (171), Tygon (179), Vinaplas-Lac (160), Vulcabond (10), Vy King (51), Wilross (187), Zerok (19)	4, 10, 12, 14, 16, 18, 19, 21, 27, 28, 29, 33, 38, 39, 40, 46, 50, 51, 60, 68, 70, 74, 80, 82, 84, 98, 106, 113, 114, 115, 123, 139, 142, 143, 145, 147, 149, 155, 160, 168, 169, 171, 176, 179, 183, 187
55. Vinyl chloride-vinylidene chloride copolymers	Ameran (82), Amercoat (4), Arcco (27), Breon (29), Carboline (33), Corogard (115), Corrocote (38), Geon (81), Goodrich, B.F. (82), Inceloid (12), Midland (113), Perma-Skin (50), Placco (27), Polyco (27), Rand (149), Reslac (27), Resyn (123), Saran (54), Vinaplas-Lac (160), Vinol (42), Wiflex (70), Wilross (187)	4, 12, 14, 27, 28, 29, 33, 38, 40, 42, 50, 54, 57, 70, 80, 81, 82, 98, 113, 123, 139, 143, 147, 149, 160, 176, 183, 187
56. Vinyl ether resin	Oppanol C (129), PVI (76), PVM (76), Wilross (187)	14, 76, 129, 187
57. Vinyl formal resins	Formvar (164), Schenectady (159)	80, 159, 160, 164
58. Vinyl pyrrolidone resin	PVP (76)	76

LIST OF MANUFACTURERS AND SUPPLIERS OF COATINGS AND RESINS FOR COATINGS*

1. Acme Resin Corp., 1401 Circle Ave., Forest Park, Ill. (C)
2. Adhesive Products Corp., 1660 Boone Ave., New York 60, N. Y. (C)
3. Alkydol Laboratories, Inc., 3242 S. 50th Ave., Cicero 50, Ill. (R)
4. Amercoat Corp., 4809 Firestone Blvd., South Gate, Calif. (C)
5. American Agile Corp., P.O. Box 168, Bedford, Ohio (C)
6. American Alkyd Industries, Broad and 14th Sts., Carlstadt, N. J. (C)
7. American-British Chemical Supplies, Inc., 180 Madison Ave., New York 16, N.Y. (R)
8. American Cyanamid Co., 30 Rockefeller Plaza, N.Y. 20, N.Y. (R)
9. American Hard Rubber Co., New York 13, N.Y. (C)
10. American Latex Products Corp., Hawthorne, Calif. (C)
11. American Lucoflex Inc., 500 5th Ave., New York 36, N.Y. (C)
12. American Products Manufacturing Co., New Orleans, La. (C)
13. Amoco Chemicals Corp., Chicago 80, Ill. (R)
14. Angier Adhesives, Div. of Interchemical Corp., 120 Potter St., Cambridge 42, Mass. (C)
15. Aries Laboratories, Inc., 270 Park Ave., New York 17, N.Y. (C)
16. Armitage and Co., John L., 245 Thomas St., Newark 5, N.J. (C)
17. Arrow Lacquer Corp., 208 Dupont St., Brooklyn 22, N.Y. (C)
18. Atlas Coatings Corp., Long Island City 1, N.Y. (C)
19. Atlas Mineral Products Co., Mertztown, Pa. (C)
20. Atlas Powder Co., Wilmington 99, Del. (C)
21. Bakelite Co., Div. of Union Carbide and Carbon Corp., 30 E. 42nd St., New York 17, N.Y. (R)
22. Barrett Div., Allied Chemical and Dye Corp., 40 Rector St., New York 6, N.Y. (R)
23. Belding Corticelli Industries, Chemicals Div., 1407 Broadway, New York 18, N.Y. (C)
24. Biggs Co., Inc., Carl H., Los Angeles 64, Calif. (C)
25. Bischoff Chemical Corp., Ivoryton, Conn. (C)
26. Booty Resineers, Inc., 112 Jefferson St., Newark, Ohio (C)
27. Borden Co., The, Chemical Div., 350 Madison Ave., New York 17, N.Y. (R)

Fibers Chart

PROPERTIES*	ACETATE	TRIACETATE	SAPONIFIED ACETATE		CUPRAMMONIUM RAYON
	Regular	*(Arnel)*†	*Fortisan*†	*Fortisan-36*	
Dimensions of fibers					
1. Continuous length	Yes	Yes	Yes	Yes	Yes
2. Staple length, in.	9/16 to 7	Any std. commercial length	–	–	1.5-7
3. Width, microns	11-73	17-40	3-9	3-9	5-11
4. Specific gravity at 25°C.	1.30-1.35	1.30	1.5	1.52	1.54
Tensile properties at break					
5. Tenacity 21°C. and 65% R.H., g./denier	1.1-1.4	1.2-1.4	7.0	8+	1.7-2.3
6. Tensile strength at 21°C. and 65% R.H., p.s.i.	18,000-23,000	20,000-23,000	138,000	155,000	33,000-42,000
7. Wet, percent of strength at 21°C., 65% R.H.	60-65	67-70	85	75	59
8. Ultimate elongation at 65% R.H., percent	23-30	25-40	6	6	10-17
Recovery from strain[b]					
9. Strain, percent	2 | 20	3-10	2 | 5	2 | 5	5 | 15
10. Recovery, percent	94 | 23	88-43	75 | 63	82 | 75	48 | 32
Modulus of elasticity					
11. Static method,[c] 10^{10} dynes/cm.^{2}	3.0-4.8	3.5-5.2	20.4-24.5	34	9.2
12. Static method,[c] g./denier	26-41	35-45	152-183	250	68
13. Velocity of sound method,[e] 10^{10} dynes/cm.^{2}	6.1	–	–	–	–
14. Velocity of sound method,[e] g./denier	52	–	–	–	–
15. Stiffness,[f] average, g./denier	5.2	5.3	120	135	14
16. Toughness index,[g] g.-cm./denier cm.	0.19[g]	.18	0.21	0.26	0.14
17. Moisture regain at 21°C., 65% R.H., percent	6.3-6.5	3.2	10.0-11.5	9-10	14-15
18. Swelling in water,[h] percent	15-30	–	18-26	–	99-134
Refractive index					
19. Epsilon[i]	1.478	1.472	1.547	1.551	1.548
20. Omega[j]	1.473	1.471	1.523	1.520	1.527
21. Dielectric constant[y]	3.8 at 60 cy. (0% R.H.) 5.0 at 60 cy. (50% R.H.)	4.1 at 60 cy. (dry) 3.7 at 10^6 cy. (dry)	–	–	–
22. Effect of age	Virtually none	Virtually none	Similar to cotton		Virtually none
23. Effect of heat, °F.	Becomes sticky 350 to 375	Scorching resistance exceptionally high; 86% of original strength retained after 11 days' exposure at 302	Similar to cotton		Decomposes 300; burns readily
24. Softening temperature, °F.	375-400 Melts at 500	Non-heat-treated softening point as measured in terms of safe ironing temperature 365. Heat-treated 465-482°, melting point 572.	–		–
25. Effect of sunlight, prolonged exposure	Loss of tensile strength No discoloration	Highly resistant under glass; unprotected sunlight exposure somewhat less.	Similar to cotton		Loss of tensile strength
26. Resistance to moths[l]	Not attacked	Not attacked	Not attacked		Not attacked
27. Resistance to mildew[m]	Resistant	Highly resistant; essentially undamaged by 12-wk. soil burial test	Similar to cotton		Attacked
28. Effect of strong acids	Decomposed	Degraded	Decomposed		Disintegrated by hot dilute or cold concentrated
29. Effect of weak acids	Dissolved by certain weak organic acids, such as acetic	Unaffected by dilute solutions of weak acids	Resistant		Similar to viscose
30. Effect of strong alkalies	Saponified	Slowly saponified; only slightly affected at low temperatures (mercerizing conditions)	Swelling and mercerization; loss of strength in hot conc.		Swelling and loss of strength
31. Effect of weak alkalies	Little or no effect for short periods; cold. Saponification on long standing or hot.	Little or no effect at 9.5 pH at 200°F. under normal scouring conditions	Little effect		Little effect if dilute
32. Effect of organic solvents	Insoluble in dry cleaning solvents generally; swollen or dissolved in acetone, ethyl acetate, many ketones and esters, glacial acetic acid, phenol, and some chlorinated solvents. Softened in alcohol	Unaffected by dry cleaning solvents; swollen by acetone, other ketones and trichloroethylene. Soluble in methylene chloride	Resistant		Resistant
33. Dyes used	Dispersed acetate dyestuffs; selected vats and azo colors; some acid and basic dyes; pigment dyes; solvent (swelling) dyeing	Selected dispersed "acetate" dyestuff; developed azo colors; selected sulfur and vat colors; solvent (swelling) dyeing	Dyes used for cotton; direct colors, sulfurs, naphthols, and vat dyes		Same as for viscose rayon

Synthetic Fibers[a]: Manufacturers[v] and Trade Names

Acetate

Avisco. American Viscose, 1617 Pennsylvania Blvd., Philadelphia 3, Pa.

Celanese, Celaperm, Lanese. Celanese Corp. of America, 180 Madison Ave., New York 16, N.Y.

DuPont acetate. E.I.duPont de Nemours & Co., Inc., Wilmington 98, Delaware.

Teca, Estron, Chromspun. Estron and Chromspun Acetate Fiber, Eastman Chemical Products, Inc., Kingsport, Tennessee.

Triacetate

Arnel. Celanese Corp. of America, 180 Madison Ave., New York 16, N.Y.

Partially Saponified Acetate

Celcos. Celanese Corp. of America, 180 Madison Ave., New York 16, N.Y.

Rayon, Saponified Acetate

Fortisan. Celanese Corp. of America, 180 Madison Ave., New York 16, N.Y.

Rayon, Cuprammonium

Bemberg, Matesa. American Bemberg, 261 Fifth Avenue, New York 16, New York.

Rayon, Viscose

Avisco. American Viscose Corp., 1617 Pennsylvania Blvd., Philadelphia 3, Pennsylvania.

Briglo, Englo, Enka, Jetspun, Perlglo, Superenka, Tempra. American Enka Corp., 206 Madison Ave., New York 16, N.Y.

Chardonize, Hygram, Tubize. Celanese Corp. of America, 180 Madison Ave., New York 16, N.Y.

Chromaset, Duralon. Delaware Rayon Div., Greenville Mills, Inc., New Castle, Delaware.

Cordura, Super Cordura. DuPont rayon. E.I. duPont de Nemours & Co., Inc., Wilmington 98, Del.

Covingtone, Suede-Skin, Spun-Black, Superwind, Dul-Tone, Spun-Lo, Tyron, Nupron, Premier, Covinair, Lektroset. Industrial Rayon Corp., Union Commerce Bldg., Cleveland 1, Ohio.

Narco, Hi-Narco, Super-Narco, Semi-Dul, Xtra-Dul. North American Rayon Corp., 261 Fifth Ave., New York 16, N.Y.

Newbray, Newdull, Newlow. New Bedford Rayon Company, Box 908, New Bedford, Massachusetts.

Veri-Dul. Skenandoa Rayon Corp., 261 Fifth Ave., New York 16, N.Y.

Nylon

Chemstrand nylon. Chemstrand Corp., 350 Fifth Ave., New York 1, N.Y.

Dawbarn nylon. Dawbarn Brothers, Inc., Waynesboro, Va.

DuPont nylon. E. I. duPont de Nemours & Co., Inc., Wilmington 98, Delaware.

Enka, Nylenka. American Enka Corp., 206 Madison Ave., New York 16, N.Y.

Firestone nylon monofilament. Firestone Plastics Co.; Div. of Firestone Tire and Rubber Co., Pottstown, Pa.

Industrial Rayon Corp. nylon. Industrial Rayon Corp., 500 Fifth Ave., New York 36, N.Y.

Polyester

Dacron. E. I. duPont de Nemours & Co., Inc., Wilmington 98, Delaware.

Zein

Vicara. Virginia-Carolina Corp., Fiber Div., Taftville, Connecticut.

Polytetrafluoroethylene

Teflon. E. I. duPont de Nemours & Co., Inc., Wilmington 98, Del.

Vinyl Chloride-Vinyl Acetate Resin

Vinyon HH. American Viscose Corp., 1617 Pennsylvania Blvd., Philadelphia 3, Pa.

Vinylidene Chloride Resin

Bolta saran. Bolta Products, Div. of The General Tire and Rubber Co., Lawrence, Mass.

Dawbarn saran. Dawbarn Brothers, Inc., Waynesboro, Virginia.

Lus-Trus saran. Lus-Trus Corp., 884 Railroad St., Ypsilanti, Mich.; also Southern Lus-Trus Corp., 1048 Escambia St., Jacksonville, Fla.

National saran. National Plastics Products Co., Odenton, Maryland.

Velon. Firestone Plastics Co., Pottstown, Pennsylvania.

—Saran Co., Odenton, Md.

Acrylic

Acrilan. Chemstrand Corp., 350 Fifth Avenue, New York 1, N.Y.

Acrylast. Dawbarn Brothers, Inc., Waynesboro, Va.

Creslan. American Cyanamid Co., 30 Rockefeller Plaza, New York 20, N.Y.

Dynel. Carbide & Carbon Chemicals Corp., 30 East 42nd St., New York 17, N.Y.

Orlon. E. I. duPont de Nemours & Co., Inc., Wilmington 98, Delaware.

Polyethylene

DLP. Dawbarn Brothers, Inc., Waynesboro, Virginia.

Firestone. Firestone Plastics Co., Box 690, Pottstown, Pennsylvania.

Reevon. Reeves Brothers, Inc., 54 Worth Street, New York 13, N.Y.

Wynene. National Plastics Products Company, Odenton, Maryland.

Glass

Fiberglas. Owens-Corning Fiberglas Corp., Textiles Division, 16 East 56th Street, New York 22, N.Y.

Garan, Vitron. L-O-F Glass Fibers Co., 1810 Madison Avenue, Toledo 1, Ohio.

Modiglass. Modigliani Glass Fibers, Inc., 70 Pine St., New York 5, N.Y.

Pittsburgh PPG. Pittsburgh Plate Glass Co., Fiber Glass Division, One Gateway Center, Pittsburgh 22, Pa.

Unifab, Uniformat, Unirove. Ferro Corporation, Fiber Glass Division, Fiber Glass Road, Nashville 11, Tennessee.

---

[a] This compilation of the principal physical and chemical properties of the commercially important textile fibers was originally prepared for the Modern Plastics Encyclopedia by Harris Research Laboratories.

[b] Except as otherwise noted, all values for elastic recovery were obtained at 20 °C. and 65% relative humidity; rate of loading 10 g./denier/min.; duration of action of load 30 sec.; recovery time 60 sec.

[c] Except as otherwise noted, all values for static method were obtained under the same conditions described in footnote (b).

[d] Testing conditions not reported.

[e] All values by the velocity of sound method were obtained in air-dry condition.

[f] Stiffness (resistance to deformation) is the ratio of breaking stress to breaking strain, P/E, where P is the stress in grams per denier required to produce rupture and E is the strain in centimeters per gauge centimeter at breaking stress.

[g] Toughness (the ability to absorb work), expressed as a toughness index, is the work per unit (denier and length) or weight of material which would cause rupture if the stress-strain curve were a straight line: PE/2.

[h] Values pertain to cross-section area increase, essentially equivalent to volumetric swelling.

[i] Index for light vibrating parallel to the long fiber axis.

[j] Index for light vibrating perpendicular to the long fiber axis.

[l] Many materials are subject to attack by moths if they contain edible finishes.

[m] Resistance of yarns and fabrics to mildew depends in many cases upon the nature of the finishing materials used.

[n] Rate of loading 1 g./denier/minute.

[o] Stretched: rate of loading 7.5 g./denier/min.; duration of action of load 40 sec.; recovery time 60 sec.; stabilized: rate of loading 4 g./denier/min.; duration of action of load 45 sec.; recovery time 60 sec.

[p] Measurements made on uncrimped tow.

[q] Based on circular cross-sections. "Orlon" has "dog-bone" cross-section.

[r] Nylon and "Dacron" measured on Single End "Suter" Tester. "Orlon" measured on "IP-4" (16 g./d./min.).

[s] Recovery against no load, samples loaded and load released immediately, recovery within 60 seconds (75 °F., 65% R.H.).

[t] "Instron" Tester, 10% per min. rate of elongation (75 °F., 72% R.H.).

[u] $n_D/20$ °C. = 1.530 obtained on pressed disk of "Vinyon" N resin. Birefringence could not be detected in this manner.

[v] Where executive offices and plants have different locations, the addresses listed are for the executive offices.

[w] Fiber in experimental production only.

[x] Stiffness determined at yield point.

[y] Determined on film.

LIST OF MANUFACTURERS AND SUPPLIERS*

1. Biggs Co., Inc., Carl H., 2255 Barry Ave., Los Angeles 64, Calif.
2. Buckstaff Co., The, Oshkosh, Wis.
3. Capac Industries, Inc., S. Main St., Capac, Mich.
4. Coast Mfg. and Supply Co., Livermore, Calif.
5. Consoweld Corp., Wisconsin Rapids, Wis.
6. Continental Can Co., Inc., 4300 N. Port Washington Rd., Milwaukee, Wis.
7. Continental-Diamond Fibre Co., Newark, Del.
8. Decar Plastic Corp., Middleton, Wis.
9. Electro-Technical Products, Div. of Sun Chemical Corp., 113 E. Centre St., Nutley 10, N.J.
10. Emerson and Cuming, Inc., 869 Washington St., Canton, Mass.
11. Fabricon Products, Div. of Eagle-Picher Co., 1721 Pleasant Ave., River Rouge 18, Mich.; 6430 E. Slauson, Los Angeles, Calif.
12. Farley & Loetscher Mfg. Co., Dubuque, Iowa
13. Flexfirm Products, 2300 North Chico Ave., El Monte, Calif.
14. Formica Corp., The, 4614 Spring Grove Ave., Cincinnati 32, Ohio
15. General Electric Co., Coshocton, Ohio
16. Gill Corp., M.C., 1422 Potrero, El Monte, Calif.
17. Glastic Corporation, 1823 E. 40th St., Cleveland 3, Ohio
18. Haskelite Mfg. Corp., Grand Rapids 2, Mich.
19. J.P. Lewis Co., Beaver Falls, N.Y.
20. Lunn Industries, Inc., Oakwood Rd. & W. 11th St., Huntington Station, L.I., N.Y.
21. Masonite Corporation, 111 West Washington St., Chicago, Ill.
22. Mica Insulator Co., P.O. Box 1076, Schenectady 1, N.Y.
23. National Plastic Products Co., Odenton, Md.
24. National Vulcanized Fibre Co., Wilmington 99, Del.
25. Northern Plastics Corp., La Crosse, Wis.
26. Panelyte Div., St. Regis Paper Co., Enterprise Ave., Trenton, N.J.
27. Parkwood Laminates, Inc., 24 Water St., Wakefield, Mass.
28. Pioneer Plastics Corp., 28 Goodhue St., Salem, Mass.
29. Richardson Co., The, 2747 Lake St., Melrose Park, Ill.
30. Rogers Corp., Rogers, Conn.
31. Russell Reinforced Plastics Corp., 4 S. 13th St., Lindenhurst, L.I., N.Y.
32. Joseph T. Ryerson & Son, Inc., P.O. Box 8000-A, Chicago 80, Ill.
34. Spaulding Fibre Co., Inc., 310 Wheeler St., Tonawanda, N.Y.
35. Synthane Corp., Oaks, Pa.
36. Taylor Fibre Co., Norristown, Pa.; La Verne, Calif.
37. Westinghouse Electric Corp., P.O. Box 868, Pittsburgh 30, Pa.
38. Wilmington Fibre Specialty Co., New Castle, Del.
39. Woodall Industries, Inc., 7565 E. McNichols Road, Detroit 34, Mich.
40. Zenith Plastics Co., 1600 West 135th St., Gardena, Calif.
41. Ren Plastics, Inc., 3179 S. Cedar Rd., Lansing 4, Mich.

*The values for the properties in this chart are based upon maximum and minimum figures submitted by a number of manufacturers of each type of laminate. The manufacturers should always be consulted before making a choice of laminate.

[a] D numbers refer to A.S.T.M. methods.

[b] The values reported for this property depend on the size and shape of the test piece and the molding conditions. The maximum permissible service temperature will vary with the formulation of the material, design of the part, and service conditions such as amount of stressing, humidity, etc. Requirements for resistance to heat should be considered a special problem.

Low-Pressure Laminating Resins Chart

PROPERTY	SHERWIN-WILLIAMS CO., PC&C Division, 260 Madison Ave., New York 16, N.Y.						ALKYDOL LABORATORIES, INC. Chicago 50, Ill.	TECHNICRAFT CO. 1156 Commonwealth Ave., Boston 34, Mass.
Resin number	XFR-10	XFR-11	AA 5289	AA 4540	AA 4544	AA 4545	Alk-O-Flex 452	Chemiglas Casting, embedding
Identity	Rigid; general-purpose polyester	Rigid; general-purpose polyester	Flexible polyester	Fire-retardant polyester	Rigid; light-stable polyester	Non-air-inhibited polyester	Epoxy resin	Styrene polyester resin
Viscosity at 25 °C., cp.	500–885	1760–2270	100–150	320–400	500–885	500–885	9850	Adjustable
Storage life of resin	No catalyst, in dark: 40 °F.: over 1 yr. 77 °F.: over 4 mo.						–	No catalyst 40 °F.: >1 yr. 77 °F.: >9 mo. (in container)
Resin content as applied, %	66–68	66–68	66–68	66–68	66–68	66–68	–	50–75
Storage life of treated material	1% benzoyl peroxide at 77 °F. and in dark: 4 to 6 days						–	1% catalyst: 10 hr.
Curing cycle Pressure, p.s.i.	Contact and up						0–75 and up	Contact to 200
Temperature, °F.	Room temperature to 260, depending on the catalyst system and amount of resin						–	–
Time, min.	Heat cure: 1 to 30 depending on the catalyst system and amount of resin. Room temperature cure: 5 min. to several hours depending upon conditions.						–	24–48 hr. with 1% cat.; 30–40 min. with 1% cat. & promoter; 10 min. with 1% C & P plus infra-red or ultra-violet (small castings)

PROPERTY	GENERAL ELECTRIC COMPANY, 1 Plastics Avenue, Pittsfield, Mass. (see also p. 597)						EMERSON AND CUMING, INC. Canton, Mass.
Resin number	AR401	AR403	AR480	AR493	AR501	AR499	Ecco L 65. Low elec. loss
Identity	Unsaturated polyester resin						Cross-linked styrene
Viscosity at 25 °C., cp.	3,000–4,000 non-adjustable	1,700–2,700 adjustable	600–1,000 adjustable	1,700–2,700 adjustable	200–300 adjustable	600–900 adjustable	–
Storage life of resin	No catalyst, refrigerated: indefinitely No catalyst, room temperature: 4 mo. (min.)					Refrigerated: 6 mo. at 77 °F. In absence of light: 3 mo.	–
Resin content as applied, %	30 to 80						
Storage life of treated material	With 1% benzoyl peroxide 4 days at room temperature					At 77 °F.: 4 mo.	–
Curing cycle Pressure, p.s.i.	Contact to 300 (or beyond if desired)						Contact and up
Temperature, °F.	Matched-die molding and laminating: 230–260. Also room temperature cure with accelerators.					250–300	150–250
Time, min.	Heat cure: 1–30 depending upon temperature and conditions. Room temperature cure: 5 min. to several hours depending upon conditions					1–30	150 °F.: 4 hr. 250 °F.: 1 hr.

PROPERTY	THE GLIDDEN COMPANY, 11001 Madison Ave., Cleveland 2, Ohio						Silicones Div., Union Carbide and Carbon Corp., New York 17, N.Y.
Resin number	Glidpol 1001, 1005, 1012. General purpose; variable-reactivity; rigid.	Glidpol 1019, 1020. Semi-rigid, resilient	Glidpol 1017. High heat distortion; rigid.	Glidpol 1018. Fire retardant; rigid.	Glidpol 2002. Flexible.	Glidpol 4000 Series. Coating resins at 100% reactivity.	Union Carbide R-63
Identity	Unsaturated polyester resin						Silicone
Viscosity at 25 °C., cp.	600–1000	800–2200	1500	1700	100	50–2000	30–50
Storage life of resin	4 to 6 months at 77 °F.						Room temp.: >6 mo.
Resin content as applied, %	65 to 75					50 to 100	60
Storage life of treated material	2 hours to 5 days depending on catalyst used.						Catalyzed: 1–2 days.
Curing cycle Pressure, p.s.i.	Contact pressure to 800					Capable of air dry in 4 hr. Cured at elevated temperatures (200–300 °F.) in 2 to 15 min.	1000 lb.
Temperature, °F.	Room temperature to 260, depending on resin and catalysts.						340–480
Time, min.	2–5, depending on temperature, catalysts, and resin mass.						½ to 2 hr.; post-baked if cured at <400 °F.

PROPERTY	AMERICAN CYANAMID CO., 30 Rockefeller Plaza, New York 20, N.Y.						ATLAS POWDER COMPANY Wilmington 99, Del.	
Resin number	Laminac 4101, 4109, 4110, 4111, 4116, 4119, 4120, 4123, 4128. General purpose	Laminac 4134. Flexible	Laminac 4146. Fire-resistant	Laminac 4190 Series. Light stabilized	Laminac 4202. Non-volatile	Laminac 4232 4233. High heat resistant	Atlac 382. Chemical resistant	Atlac FP. Fire-resistant
Identity	Styrene modified polyesters				Diallyl phthalate modified	Triallyl cyanurate modified	Unsaturated polyester resin (solid)	
Viscosity at 25°C., cp.	200-25,000	250-275	350-400	150-300	120,000-150,000		In 35% styrene: 8000. In 50% styrene: 500	In 30% styrene: 4000
Storage life of resin	Greater than 3 months at 77°F.						Indefinite	
Resin content as applied, %	100% reactive						100 (as supplied)	
Storage life of treated material	From hours to days depending on catalyst formulation, type of resin and temperature of storage						Room temperature: 1 day up to 6 mo.	
Curing cycle Pressure, p.s.i.	From contact to 1000 or higher						Contact to 100	
Temperature, °F.	Room temperature to 275, depending upon catalyst and promoter used.				200-300	180-500	Room to 320, depending on catalyst	
Time	From 1 to 30 min. at oven temperatures to several hr. at room temperature				From 10 min. to several hours		1 min. up to 30 min., depending on conditions	

PROPERTY	SPECIALTY RESINS CO., 2801 Lynwood Road, Lynwood, Calif.					COLUMBIA-SOUTHERN CHEMICAL CORP., 1 Gateway Center, Pittsburgh 22, Pa.	AMERICAN REINFORCED PLASTICS SALES, 650 S. Spring St., Los Angeles 14, Calif.
Resin number	DurOpol 104	DurOpol 109	DurOpol 120	DurOpol 190	DurOpol 2894 CW Cold cure resin	Allyl diglycol carbonate	CTL-91-LD
Identity	Polyester-styrene	Polyester-styrene	Polyester-styrene	Polyester-styrene	Polyester-styrene	Allyl resin	Phenolic
Viscosity at 25°C., cp.	2500-3200	900-1300	800-1200	1750-2300	600-800	19.5 at 25°C. 6.4 at 70°C.	Can be adjusted
Storage life of resin	70°F., dark: >3 mo.; 105°F., dark: 14 days	75°F., dark: >4 mo.; 105°F., dark: 14 days	75°F., dark: >4 mo.; 105°F., dark: 14 days	70°F., dark: >3 mo.; 105°F., dark: 14 days	70°F., dark: >3 mo.; 105°F., dark: 14 days	No catalyst: several months; with catalyst: approx. 2 wk.	Must be refrigerated
